rod- and plate-like morphologies with homogeneous dispersion in GdBa2Cu3O7-δ. In addition, growth directions of these precipitates were found with wide angular distributions from growth direction of GdBa2Cu3O7-δ. Anisotropy of $J_c$ in the magnetic fields was probably enhanced by various growth directions and homogeneous dispersion of nanosized BHO within GdBa2Cu3O7-δ.

Introduction
Mesoporous silica, SBA-15, is one of the best candidates for the supporting material of catalytic nanoparticles because of its relative large surface area [1]. So far, various nanoparticles, such as Au, Pt and Pd, have been introduced into the pore for catalytic application [2]. The size of nanoparticles supported inside SBA-15 is restricted by that of the pore, and they are usually ranging from 2 nm and 50 nm in space. If it is necessary to anchor the nanoparticles within pores to avoid segregation / sintering of them. However, it is difficult to anchor them within pores in the case of use of deposition-precipitation method due to extreme low iso-electric point (IEP) of silica (~2). Therefore, TiO2 nanocrystals (IEP 6–8) were then introduced to anchor AuNPs [3]. In this study, EFTEM tomography was applied to examine the effectiveness of TiO2 for AuNPs.

Materials and method
Au/TiO2-SBA-15 was embedded into epoxy resin for electron microscopy and microtomated to around 30 nm thickness. EFTEM-tomography was operated at 120 kV and using Ti-L ionization edge via three-window method. Prior to EFTEM, STEM-HAADF tomography was also carried out for visualizing AuNPs and for comparison.

Result and discussion
Figure 1 shows 3D-volume of AuNPs and TiO2 nanocrystals from EFTEM-tomography. TiO2 nanoparticles in the porous material were successfully visualized using EFTEM-tomography, and local relationship between AuNPs and TiO2 nanocrystals were revealed. A large number of TiO2 nanocrystals were randomly distributed in the SBA-15. It was found that most AuNPs were directly on the exposed TiO2 nanocrystals. It implies that TiO2 nanocrystals were exposed on the surface of the pore and anchored AuNPs inside the pores. Critical current ($I_c$) of superconductor films under magnetic field is strongly influenced by dispersions and morphologies of artificial pinning centers (APCs) in general [1]. BaHfO3 (BHO) is acknowledged as the best candidates of APCs for REBCO films, which shows utmost thickness dependence and isotropic angular dependence of $I_c$ values for REBCO films [2]. Moreover, several researchers have focused on the nanostrains caused by the lattice mismatch at the interface between APCs and REBCO matrix, which are also the source for enhanced vortex pinning of the REBCO films [3]. In this study, we investigated to examine the nanostrain at the interface using spherical aberration (Cs) corrected scanning transmission electron microscopy (STEM).
