Abstract. νZ is a part of the SMT solver Z3. It allows users to pose and solve optimization problems modulo theories. Many SMT applications use models to provide satisfying assignments, and a growing number of these build on top of Z3 to get *optimal* assignments with respect to objective functions. νZ provides a portfolio of approaches for solving linear optimization problems over SMT formulas, MaxSMT, and their combinations. Objective functions are combined as either Pareto fronts, lexicographically, or each objective is optimized independently. We describe usage scenarios of νZ , outline the tool architecture that allows dispatching problems to special purpose solvers, and examine use cases.

1 An Invitation to νZ

νZ extends the functionality of Z3 [7] to include optimization objectives. It allows users to solve SMT constraints and at the same time formulate optimality criteria for the solutions. It relieves users of Z3 from writing their own loops around the solver to find optimal values. The solver integrates state-of-the-art algorithms for optimization, and it extends some of these algorithms with its own twists: For example, it includes direct support for difference logic solvers, it uses Simplex over non-standard numbers to find unbounded constraints, and it applies an incremental version of the MaxRes [11] algorithm for MaxSAT solving.

To give a first idea, we can ask to optimize the term $x + y$ under the constraints $y < 5 \wedge x < 2$ and $y - x < 1$ using the SMT query to the right. The optimal answer is given as 2 and νZ returns a model where $x = y = 1$. The example shows the `maximize` command that is added to the SMT-LIB [13] syntax.

```
(declare-fun x () Int)
(declare-fun y () Int)
(assert (and (< y 5) (< x 2)))
(assert (< (- y x) 1))
(maximize (+ x y))
(check-sat)
(get-model)
```

1.1 Optimization Commands

The full set of commands νZ adds to SMT-LIB are:

<pre> (declare-fun x () Int) (declare-fun y () Int) (define-fun a1 () Bool (> x 0)) (define-fun a2 () Bool (< x y)) (assert (=> a2 a1)) (assert-soft a2 :dweight 3.1) (assert-soft (not a1) :weight 5) (check-sat) (get-model) </pre>	<pre> (declare-fun x () Int) (declare-fun y () Int) (assert (= (+ x y) 10)) (assert (>= x 0)) (assert (>= y 0)) (maximize x) (maximize y) (set-option :opt.priority box) (check-sat) </pre>
--	---

Fig. 1. Maximize $3.1 \cdot a2 + 5 \cdot \overline{a1}$. νZ finds a solution where $y \leq x \leq 0$. **Fig. 2.** νZ produces two independent optima $x = 10$, respectively $y = 10$.

- (`maximize  $t$`) - instruct the solver to maximize t . The type of the term t can be either Integer, Real or Bit-vector.
- (`minimize  $t$`) - instruct the solver to minimize t .
- (`assert-soft  $F$  [:weight  $n$  | :dweight  $d$ ] [:id  $id$ ]`) - assert soft constraint F , optionally with an integral weight n or a decimal weight d . If no weight is given, the default weight is 1 (1.0). Decimal and integral weights can be mixed freely. Soft constraints can be furthermore tagged with an optional name id . This enables combining multiple different soft objectives. Fig. 1 illustrates a use with soft constraints.

1.2 Combining Objectives

Multiple objectives can be combined using lexicographic, Pareto fronts or as independent box objectives.

Lexicographic combinations: By default, νZ maximizes objectives t_1, t_2 subject to the constraint F using a lexicographic combination. It finds a model M , such that M satisfies F and the pair $\langle M(t_1), M(t_2) \rangle$ is lexicographically maximal. In other words, there is no model M' of F , such that either $M'(t_1) > M(t_1)$ or $M'(t_1) = M(t_1), M'(t_2) > M(t_2)$.

Pareto fronts: Again, given two maximization objectives t_1, t_2 , the set of Pareto fronts under F are the set of models $M_1, \dots, M_i, \dots, M_j, \dots$, such that either $M_i(t_1) > M_j(t_1)$ or $M_i(t_2) > M_j(t_2)$, and at the same time either $M_i(t_1) < M_j(t_1)$ or $M_i(t_2) < M_j(t_2)$; and for each M_i , there is no M' that dominates M_i . νZ uses the Guided Improvement Algorithm [14] to produce multiple objectives. Fig. 3 illustrates a use where Pareto combination is specified.

Boxes: Box objectives, illustrated in Fig.2 are used to specify independent optima subject to a formula F . They are used in the Symba tool [9]. The box combination of objectives t_1, t_2 requires up to two models M_1, M_2 of F , such that $M_1(t_1)$ is the maximal value of t_1 and $M_2(t_2)$ is the maximal value for t_2 .

1.3 Programming Optimization

The optimization features are available over Z3's programmatic APIs for C, C++, Java, .NET, and Python. There is furthermore a library available as an example that plugs into the Microsoft Solver Foundation (MSF). Fig. 3 shows an example using the Python API to generate Pareto optimal solutions. Fig. 4 shows an OML model used by MSF.

```
x, y = Ints('x y')
opt = Optimize()
opt.set(priority='pareto')
opt.add(x + y == 10, x >= 0, y >= 0)
mx = opt.maximize(x)
my = opt.maximize(y)
while opt.check() == sat:
    print mx.value(), my.value()
```

```
Model[
  Decisions[
    Reals[-Infinity, Infinity], xs, xl ],
  Constraints[
    limits -> 0 <= xs & 0 <= xl,
    BoxWood -> xs + 3 * xl <= 200,
    Lathe -> 3 * xs + 2 * xl <= 160 ],
  Goals[
    Maximize[ $ -> 5 * xs + 20 * xl ]]]
```

Fig. 3. Pareto optimization in Python. νZ produces all 11 Pareto fronts.

Fig. 4. OML model used by MSF.

1.4 MILP, MaxSAT, CP and SMT

Efficient mixed integer linear solvers are backbones of several highly tuned tools, such as CPLEX and Gurobi, used in operations research contexts. Being able to state and solve optimization objectives in the context of logical constraints has also been well recognized in the SMT community [12,5,15,8] and it is a recurring feature request for Z3 as well. We briefly outline a use case in Section 4, and through this experience we observed a need for more abstract and flexible ways of modeling problems than exposed by OML used by the Microsoft Solver Foundation (MSF), where flexible Boolean combinations of constraints, which empower end-users to refine models, are afterthoughts. By making νZ generally available, we hope to make it easier for existing users to use Z3, for instance [2], and to fuel further applications that benefit from the flexibility and expressive power of Z3's SMT engines, including theory support and quantifiers, with the convenience of built-in support for (reasonably tuned) optimization algorithms. In return, we anticipate that new applications from SMT users can inspire advances in areas such as non-linear arithmetic, mixed symbolic/numerical algorithms, and combinations with Horn clauses.

1.5 Resources

The full source code of νZ is available with Z3 from <http://z3.codeplex.com>, the sources compile on all main platforms, there is an online tutorial on <http://rise4fun.com/z3opt/tutorial/>, and a companion paper [3] describes details of algorithms used in νZ .

2 Architecture

Fig. 5 gives an architectural overview of νZ . The input SMT formulas and objectives are rewritten and simplified using a custom strategy that detects 0-1 integer variables and rewrites these into Pseudo-Boolean Optimization (PBO) constraints. Objective functions over 0-1 variables are rewritten as MaxSAT problems⁴. If there are multiple objectives, then νZ orchestrates calls into the SMT or SAT cores. For box constraints over reals, νZ combines all linear arithmetic objectives and invokes a single instance of the OptSMT engine; for lexicographic combinations of soft constraints, νZ invokes the MaxSAT engine using multiple calls.

Fig. 5. νZ system architecture

3 Internals

OptSMT: We have augmented Z3’s dual Simplex core with a primal phase that finds maximal assignments for reals. It also improves bounds on integers as long as the improvements are integral. It is used, similarly to [15,9], to improve values of objective functions. A similar primal Simplex solver is also accessible to Z3’s difference logic engines. νZ discovers unbounded objectives by using non-standard arithmetic: It checks if $t \geq \infty$ is feasible, over the extension field $R \cup \{\epsilon, \infty := 1/\epsilon\}$. This contrasts the approach proposed in [9] that uses a search through hyper-planes extracted from inequalities.

νZ also contains a Pseudo-Boolean theory solver. It borrows from [4,1] for simplification, generating conflict clauses, and incrementally compiling into small sorting circuits. It also adds an option to prune branches using dual simplex.

MaxSMT: νZ implements several engines for MaxSAT. These include WMax [12], MaxRes [11], BCD2 [10], MaxHS [6]. WMax uses a specialized theory solver of

⁴ using the correspondence: $\text{maximize } c_1 \cdot x_1 + c_2 \cdot x_2 \equiv (\text{assert-soft } x_1 : \text{weight } c_1), (\text{assert-soft } x_2 : \text{weight } c_2)$

costs, also explored in [5]. The solver associates penalties with a set of tracked propositional variables. It then monitors the truth assignments to these variables, as given by the SAT solver. The cost is incremented when a tracked variable is assigned to *false*. The solver creates a conflict clause when the cost exceeds the current optimal value. WMax can be interrupted at any point with a current upper bound. Our implementation of MaxRes generally performs much better than WMax. MaxRes increments a lower bound when there is an unsatisfiable core of the soft constraints. It then replaces the core $F_1, \dots, F_k$ with new soft constraints $F'_1, F'_2, \dots, F'_{k-1}$ using the equations:

$$F'_1 = F_2 \vee F_1, \quad F'_2 = F_3 \vee (F_1 \wedge F_2), \quad \dots, \quad F'_{k-1} = F_k \vee ((F_1 \wedge F_2) \wedge \dots \wedge F_{k-1}) .$$

SAT: νZ reduces Pseudo-Boolean formulas to propositional SAT by converting cardinality constraints using sorting circuits, using a Shannon decomposition (BDDs) of simple PB inequalities and falling back to bit-vector constraints on inequalities where the BDD conversion is too expensive. This transformation is available by ensuring that the option `:opt.enable_sat` is `true`. For benchmarks that can be fully reduced to propositional SAT, MaxRes uses Z3's SAT solver.

4 A use for νZ

As a driving scenario for νZ we used an experimental warehouse manager in the context of Microsoft Dynamics AX. The objective is to reduce cost by optimizing how shipments are distributed on trucks, reducing the number of trucks, the distance traveled by the truck while maximizing the amount of goods delivered. AX can deliver the standard constraints and cost functions, e.g., weight and volume of a truck, but users often want to be more specific. For example, frozen foods need to be in a cooled truck and cannot be packed together with chemicals. The expressive power and convenience of SMT is useful: these constraints can be formulated as a Boolean combination of linear constraints over 0-1 variables, while the objective functions we considered could be expressed as lexicographic combinations of a couple of cost functions. Such cost functions are expected to evolve when users learn more about their usages. The abstraction layer of the models provides this flexibility.

4.1 Experience

We evaluated νZ on a cross-section of benchmarks used in MaxSAT competitions, from Z3 users, and from recent publications. Table 1 summarizes a selected evaluation. Motivating examples from users included strategy scheduling for Vampire (MaxSAT) that are easy with the new MaxSAT engine, but used to be hard for the bisection search used by Vampire. Likewise, Cezary Kaliszyk has used Z3 to tune his portfolio solver using linear arithmetic constraints. His systems are significantly more challenging (take days to run). In this case WMax offers partial solutions during search. Elvira Albert tried using Z3 for finding

longest paths, her benchmarks are called bb (≈ 300 clauses), chat ($\approx 3K$ clauses) and p2p ($\approx 30K$ clauses), and we summarize timing for bb and chat below. The p2p category remains really hard. Korovin and White experimented with encoding RNA alignment into MaxSAT, and Pandya and Bresler encoded DNA alignment problems into MaxSMT over LIA. Many problems remain challenging, including material discovery benchmarks from Ronan Le Bras, Pareto problems from Oded Maler and even benchmarks from the pure Pseudo-Boolean domain ⁵.

Source	Category	Solved instances	Time
MaxSAT 2014 wpms industrial track	MaxSAT	361/410	0.5-1800s

A Demonstration

We take a quick tour on available features in νZ . This section is based on the online tutorial at <http://rise4fun.com/Z3Opt/tutorial/guide>. Please visit the online playground for a quick try at νZ . More details of internals in νZ are also available in a paper [3] that accompanies an invited talk at SCSS 2014. The paper describes, at a high level, the algorithms used for different optimization strategies in νZ .

Linear Arithmetic

Using the example in Fig. 2, νZ returns two independent values 10 and 10 for two objectives x and y .

This example can be reproduced at <http://rise4fun.com/Z3Opt/o7h>.

Soft Constraints

The example in Fig. 1 demonstrates soft constraints with integral and decimal weights. νZ gives an optimal model where the total weight equals to 3.1 and $x = y = 0$.

Programmatic APIs

νZ 's APIs are available for multiple languages. This section presents programmatic APIs using a few F# code snippets.

Optimization features are facilitated through the new Optimize solver. As being shown in Fig. 6, combining objectives can be set via solver parameters. `MkMinimize` and `Value` are used to set optimization goals and retrieve optimal values respectively (see Fig. 7).

PB constraints are available via `MkAtMost` and `MkPBL` commands (see Fig. 8). They allow users to express some problems in a more concise manner. Soft constraints can be sent to the solver using the `AssertSoft` command. As Fig. 7 demonstrated, users can employ `Check` and `Value` methods for getting optimal values.

```

use context = new Context()
let solver = context.MkOptimize()

let param = context.MkParams()
param.Add("priority", "pareto")
solver.Parameters <- param

let cost =
  ys
  |> Array.map2 ( *. ) costs
  |> add
  |> solver.MkMinimize
match solver.Check() with
| Status.SATISFIABLE ->
  Some cost.Value
| _ -> None

```

Fig. 6. Combining objectives in F#.

Fig. 7. Getting minimized cost in F#.

```

let mkAtmost k bs =
  context.MkAtMost(bs, uint32 k)

for xi in xs do
  solver.Assert (mkAtmost 1 xi)

let serverNum =
  seq {
    for j in 1..n ->
      let yj = context.MkNot(ys.[j-1])
      server.AssertSoft(yj, 1u,
        "num_servers")
  } |> Seq.last

```

Fig. 8. Creating PB constraints in F#.

Fig. 9. Asserting soft constraints in F#.

The code fragments above are parts of a complete case study. More details can be found in the introductory blog post at <http://lonelypad.blogspot.dk/2014/08/f-and-linear-programming-introduction.html>.

Microsoft Solver Foundation plugin

```

SolverContext context = SolverContext.GetContext();
Model model = context.CreateModel();
Decision x1 = new Decision(Domain.RealRange(0, 2), "x1");
Decision x2 = new Decision(Domain.RealRange(0, 2), "x2");
Decision z = new Decision(Domain.IntegerRange(0, 1), "z");
model.AddDecisions(x1, x2, z);
model.AddConstraint("Row0", x1 - z <= 1);
model.AddConstraint("Row1", x2 + z <= 2);
Goal goal = model.AddGoal("Goal0", GoalKind.Maximize, x1 + x2);
Solution solution = context.Solve(new Z3MILPDirective());

```

Fig. 10. Using νZ MSF plugin in C#.

νZ is also available as a plugin to MSF framework. It allows users to take advantage of MSF's comprehensive infrastructure. For example, users are able

to run multiple solvers in parallel with νZ inside MSF. The plugin plays a vital role in bootstrapping νZ by comparing it with other solvers in MSF.

Case study

In this section, we use the scenario of a warehouse manager to demonstrate how νZ can be used for solving problems inspired by Dynamics AX scenarios. Suppose that there are a number of goods that need to be shipped to customers. These goods have specific destinations and requirements as shown in Table 2.

Shipment no.	Weight(kg)	Volume (m^3)	Requirement	Zip code
1	400	300	Dry	2112
2	300	350	Fresh	2100
3	220	160	Dry	2103

Table 2. Shipments that requires transportation.

Table 3 describes trucks along with their capacities, tentative destinations and associated costs. The constraints are:

1. Shipments have to fit in the capacities given by the trucks.
2. Product requirements have to be fulfilled.
3. Shipments are delivered to correct addresses (zip codes).

We can state the goals in their order of priorities (1) Use as few trucks as possible (2) Minimize the total cost for transportation. The scenario is a variant of a bin packing problem. See also the ESICUP Challenge.

Truck no.	Weight(kg)	Volume (m^3)	Requirement	Zip codes	Initial cost (USD)
1	777	700	Fresh	2100, 2103	100
2	450	1000	Dry	2100, 2103, 2112	120
3	600	460	Dry	2100, 2112	130

Table 3. Available trucks for transportation.

The constraints and goals can be modeled directly as 0-1 variables. Let the 0-1 variable x_{ij} denote that shipment i is packed into truck j . Each shipment has to be in exactly one truck.

Let 0-1 variable y_j denote that truck j is in use. Trucks are used if something is packed into them:

Here we describe weight as examples of capacity constraints. There are similar constraints for volumes.

To keep this example simple we here treat zip codes as fixed costs. The goals can be modeled as in Fig. 14. Note that we would like to minimize the number

```

(assert (= (+ x_1_1 x_1_2 x_1_3) 1))
(assert (= (+ x_2_1 x_2_2 x_2_3) 1))
(assert (= (+ x_3_1 x_3_2 x_3_3) 1))

```

Fig. 11. Each shipment is in only one truck.

```

(define-fun imax ((a Int) (b Int)) Int (if (> a b) a b))
(assert (= y_1 (imax (imax x_1_1 x_2_1) x_3_1)))
(assert (= y_2 (imax (imax x_1_2 x_2_2) x_3_2)))
(assert (= y_3 (imax (imax x_1_3 x_2_3) x_3_3)))

```

Fig. 12. Truck j (y_j) is in use.

of used trucks and minimize total cost, so in MaxSMT these goals are equivalent to maximizing number of unused trucks and maximizing saving.

Although we express the problem via 0-1 variables, νZ translates it via Pseudo-Boolean constraints (**opt.elim_01=true** by default). In this case νZ uses the Pseudo-Boolean solver and solves a MaxSMT problem. Furthermore, by ensuring that **opt.enable_sat=true**, **opt.maxsat_engine=maxres**, νZ translates Pseudo-Boolean constraints to SAT and uses a pure MaxSAT solver.

The example illustrates a fair amount of flexibility in formulating constraints, and control over the most suitable back-end for these constraints.

Selected evaluation details

In Fig. 15, the two top graphs show comparison with νZ and the best solvers in MaxSAT 2014 competition. Note that νZ is presently not fine-tuned as some of these competition entrants are, but performs quite respectably. What is not shown is performance of other solvers entering the competition and performing on par or worse than νZ . The bottom graph shows relative comparison of νZ with and without the Symba approach of finding unbounded objectives. The experience indicates that searching separately for unbounded objectives does not really help.

```

(assert (<= (+ (* 400 x_1_1) (* 300 x_2_1) (* 220 x_3_1)) (* 777 y_1)))
(assert (<= (+ (* 400 x_1_2) (* 300 x_2_2) (* 220 x_3_2)) (* 450 y_2)))
(assert (<= (+ (* 400 x_1_3) (* 300 x_2_3) (* 220 x_3_3)) (* 600 y_3)))

```
