The price fluctuations of rare earth metals and the uncertainty in their availability has generated an increased interest in ferrite magnet machines. The influence of temperature on BH characteristics of the ferrite magnet differ considerably from that of the rare earth magnet and hence, requires a different approach when deciding their operating point. In this work, laboratory measured BH curves of a ferrite magnet are used for estimating the possibility of demagnetization in a segmented axial torus (SAT) permanent magnet brushless DC (PMBLDC) motor. The BH characteristics for different temperatures have been used to study the performance variation of the ferrite magnet SAT PMBLDC motor with temperature. A detailed analysis is carried out to ensure that, the designed ferrite magnet motor is capable of delivering the specified torque throughout the operating speed, without any irreversible demagnetization of magnets. It has been shown that the ferrite magnet PMBLDC motor operation is influenced by the magnet temperature and the maximum motor speed for a given load torque decreases as the magnet temperature drops.

Index Terms—Demagnetization, ferrites, permanent magnets, brushless Machines, permanent magnet machines.

I. INTRODUCTION

IN recent years, there has been an uncertainty in the availability and the price of rare earth (RE) metals used in high energy magnets [1]. This sets stage for renewed interest in the research of ferrite magnet machines [2]–[6] as ferrites are commonly available. The main challenges in substituting the RE magnet with the ferrite are its low remanence (B_r) and coercivity (H_c). Low B_r implies a lower magnetic loading and low H_c imparts restriction on the maximum electric loading to prevent demagnetization of the magnet, thus limiting the power density of the ferrite magnet machines. Most of solutions proposed to address this limitation involve placing more magnets in rotor to enhance the air gap flux density [7], [8].

Different aspects of magnet in operation such as reversible and irreversible demagnetization as a result of armature reaction and temperature induced operating point shift on the performance of PM machine have been researched extensively for RE magnets [9]–[12]. In most of these situations, ferrite magnets behave different from RE magnets, because the coercivity of ferrite magnets increase with temperature; in other words, ferrite magnets have a positive temperature coefficient and RE magnets have a negative temperature coefficient for coercivity. The remanence of both magnets decrease with temperature. Moreover, the knee point in demagnetization characteristics appears at low temperature for ferrite magnets and at higher temperature for RE magnets. In applications such as direct drive hub motors, heat from magnets are dissipated rapidly to the surrounding because of their positioning in outer casing and therefore, the possibility of high temperature demagnetization when using RE magnets are less. In contrast, for ferrite magnets used in a similar

motor configuration, the inrush current at start can be seen as critical aspect from the magnet perspective, especially at low ambient temperatures, where the risk of demagnetisation is the highest.

Though the design of ferrite magnet machines is discussed extensively in literature [2]–[6], [8], [13], [14]; the performance variation of ferrite magnet PM brushless DC (PMBLDC) motors with temperature has not been examined in detail. Also, there is a lack of systematic approach presented for identifying the leeway for armature reaction with respect to irreversible demagnetization. The work presented in [15] discusses the effect of temperature on torque profile of a ferrite PMBLDC motor with the help of finite element (FE) electro-magnetic and thermal model. In [8], the authors described a possible demagnetization due to load line intersecting beyond the knee point of a ferrite magnet at low temperature. In [16], the authors used the flux density distribution in magnets to estimate the level of demagnetization in a PM synchronous generator and also calculated the performance variation with temperature. In [6], the authors used BH curve of ferrite magnet corresponding to the lowest operating temperature to ensure that the field weakening operation is not causing any irreversible demagnetization in a PM synchronous motor. However, authors did not evaluate the performance variation with temperature. In [17], the authors used manufacturer supplied temperature coefficient of B_r and H_c of ferrite magnet to evaluate the performance of a line-start PM machine for different operating temperatures.

This paper uses laboratory measured BH characteristics of a ferrite magnet to evaluate the margin of safety to irreversible demagnetization in a segmented axial torus (SAT) PMBLDC motor. In addition, BH characteristics of the ferrite magnet for different temperatures have been used to study the performance variation of the SAT PMBLDC motor with temperature.

II. MEASURED BH CHARACTERISTICS OF FERRITE MAGNET

This study has been carried out using a commercially available ferrite magnet and the specification from the product data sheet is shown in Table I. The BH characteristics of the ferrite magnet have been measured for temperatures starting from -20°C to 100°C . The second quadrant of the characteristics are shown in Fig.1 and each data point is the average value of measurements on five samples. Each curve in Fig.1, corresponding to a temperature, is traced from three hundred to five hundred data points. The only unexpected behaviour observed is corresponding to the room temperature (24°C) measurements and the curve is found to have knee point earlier than that of -20°C measurements. The second quadrant knee point exists for all temperatures below 70°C .

With regard to PM machine design, the critical value of demagnetizing field that the magnet can be exposed to without any permanent loss in remanence can be found from the variation of differential permeability. Differential permeability is defined as the slop (dB/dH) of BH curve [18]. Differential permeability of the ferrite magnet material is plotted against the magnetizing field for different temperatures in Fig.2. It is clear from the figure that, the dB/dH remains constant until 250 kA m^{-1} and its values at lower temperatures are changing

Fig. 2. Differential permeability variation with magnetizing field of the ferrite magnet

initially. Therefore, it can be concluded that, the ferrite magnet used in this study can safely withstand a demagnetizing field or an armature reaction field up to 250 kA m^{-1} .

III. SEGMENTED AXIAL TORUS PERMANENT MAGNET BRUSHLESS DC MOTOR

A SAT PMBLDC motor with ferrite magnet as rotor poles is designed to study the extent of demagnetization under severe armature reaction. The schematic of SAT PMBLDC motor is shown in Fig.3. The SAT motor topology [19]–[21] is a variation of torus slotted north-south (NS) axial flux motor (AFM) topology and has no stator yoke. The magnetically separated teeth can be wound separately before assembly and this ensures high fill factor and short end turn resulting in an efficiency improvement [22]. This add to improved torque density that comes with AFM topology [21]. A pole/slot combination of $P = N_s \pm 2$ has been selected to reduce the cogging torque [23]. In addition, a single-layer winding is opted as they are more suitable for BLDC motor operation [23]. The specification and main geometrical dimensions of the motor are listed in Table II. The motor will be used in an electric two-wheeler with maximum speed of 32 km h^{-1} . In order to attain the maximum speed of vehicle, the motor should produce a torque of 12 N m at 330 rpm .

IV. ESTIMATION OF DEMAGNETIZATION LEVEL OF FERRITE MAGNET IN OPERATING CONDITION

As explained in earlier sections, the ferrite magnet is more susceptible to demagnetization at lower temperatures and for this reason, the BH curve of ferrite magnet at -20°C is used for demagnetization study. The 3D FE static analysis is carried out for two values of peak armature currents 20 A and 200 A , corresponding to the full load and ten times the full load respectively. In [10], the authors proved that both anti-parallel and perpendicular field components to the direction of magnetization are necessary to accurately estimate the level of demagnetization. Therefore, $|H|$ and not $|B|$ field distribution is

Fig. 3. Schematic of ferrite magnet SAT PMBLDC motor (1. end cover, 2. rotor yoke, 3. magnets, 4. stator winding, 5. stator core and 6. wheel rim).

TABLE II

THE SPECIFICATION AND GEOMETRICAL DIMENSIONS OF FERRITE MAGNET SAT PMBLDC MOTOR

Parameter	Value
The rated voltage	48 V
The rated power output	700 W
The rated torque	20 N m
Outer diameter of the motor	275 mm
Diameter ratio	0.45
Axial length of the motor	65.5 mm
Number of poles	16
Number of slots	18
Gross slot fill factor	0.5
Thickness of magnet poles	7.5 mm
Length of air gap	0.4 mm
Number of turns per coil	30
Diameter of a coil turn	2.68 mm

used in this study. Further, in [24], [25], the authors concluded that the edges and area of permanent magnet exposed to air gap are more susceptible to demagnetization than the inner volume. The demagnetizing field acting on the entire magnet disc is shown in the part (a) of Fig.4 and 5 and the field on a single pole is shown in the part (b) of the same figures. At ten times the rated current, 48 % of magnet volume is experiencing a demagnetizing field value more than 250 kA m^{-1} and hence nearly half of the magnet disc will be demagnetized. It is clear from figures that at rated current levels only a small volume of magnet located in inter polar region will experience $|H|$ field approaching critical value of 250 kA m^{-1} for the presented design.

V. PERFORMANCE VARIATION OF PMBLDC MOTOR WITH TEMPERATURE

Besides the shift in knee point, the remanence also varies with temperature for the ferrite magnet as shown in Fig.1. The B_r diminishes by more than 10% when temperature rises from -20°C (the lowest ambient temperature considered) to a steady state magnet temperature under load (assumed to be between 55 to 70°C), and this variation will have an impact on the motor performance. A series of static FE analysis is carried out to find the flux linkage of a phase as a function of rotor

Fig. 4. Demagnetizing field distribution for an armature current of 20 A in (a) 16-pole disc and (b) a pole

Fig. 5. Demagnetizing field distribution for an armature current of 200 A in (a) 16-pole disc and (b) a pole

Fig. 6. The variation of flux linkage of a phase with rotor position for different armature currents at a magnet temperature of -20°C

position and armature current and results are shown in Fig.6 for a magnet temperature of -20°C . As the rotor rotates, flux linkage variations will induce an EMF in the winding and the instantaneous EMF induced per phase (e_{ph}) can be calculated as

$$e_{ph} = \frac{d\psi}{dt} = \frac{d\psi}{d\theta} \times \frac{d\theta}{dt} = \psi' \times \omega \quad (1)$$

where, ψ is the flux linkage per phase, θ is the rotor position and ω is the angular velocity. The variation of ψ' with rotor

Fig. 7. The variation of ψ' with rotor position for different armature currents at a magnet temperature of -20°C

Fig. 8. The variation of the average EMF constant with armature current for different magnet temperatures

position for different armature current is shown in Fig.7. In three-phase PMBLDC motor, only two phases conduct at the same time. Therefore, phase-1 and phase-3 conduct for 30 to 90 elec. Deg and phase-1 and phase-2 conducts for 90 to 150 elec. Deg as highlighted in Fig.7. The average EMF generated per phase of a PMBLDC motor (E_{ph}) can be expressed as

$$E_{ph} = K_e \times \omega \quad (2)$$

where, K_e is the EMF constant of a PMBLDC motor. The EMF constant can be derived from the flux linkage variation by comparing (1) and (2) as

$$K_e = \text{mean}(\psi') \quad (3)$$

The variation of EMF constant with armature current for different temperature, plotted in Fig.8, shows the effect temperature on K_e .

A dynamic model of three-phase PMBLDC motor is developed based on models presented in [26]–[29]. The model uses a 3D look-up table of EMF constants as a function of rotor position and armature current to calculate the rotational EMF at a magnet temperature. The phase inductances obtained from the FE model of the motor is included in the model, to account for the effect of transformer EMF. The model neglects the temperature variation of winding resistance as the maximum

Fig. 9. Torque delivered at shaft vs. speed curves of the ferrite magnet PMBLDC motor for different magnet temperatures

Fig. 10. The RMS value of phase current vs. speed curves of the ferrite magnet PMBLDC motor for different magnet temperatures

possible change in winding loss for the temperature range considered here is less than 10 W. The core loss value of 35 W in rotor yoke and stator teeth is calculated by applying steinmetz equation to the flux density distribution obtained from FE model of the SAT PMBLDC motor.

The torque vs. speed characteristics of the designed motor obtained from the simulation of dynamic model are shown in Fig.9. It is found that the motor operation beyond the base speed varies considerably with the magnet temperature and the maximum motor speed for a given load torque decreases with colder magnets. Still, the presented design will meet the torque requirement for accelerating the vehicle to the maximum speed throughout the range of temperature considered in this study. The RMS value of the phase current of the machine plotted against speed of the motor is shown in Fig.10. The weakened magnet field due to drop in remanence at higher temperature implies a reduced back EMF, which results in higher current throughout the speed range considered. The increased current at higher temperature gives rise to higher copper losses and reduced efficiency as shown in Fig.11. This trend reverses beyond the base speed as the torque increases with temperature for a given speed. This results in higher output power and hence, an improved efficiency in spite of drawing more current.

Fig. 11. The efficiency vs. speed curves of the ferrite magnet PMBLDC motor for different magnet temperatures

The impact of temperature dependence of ferrite magnet motor on system performance requires accurate modelling of power converters and controllers. The motor discussed is designed for a low cost powertrain of electric two-wheelers and in such applications closed loop controls are not usually implemented due cost constraints. Nevertheless, the presented study with consideration of the motor alone can give controller designers a better outlook into the performance variation with temperature beyond the base speed, which will be helpful in designing a control strategy for mitigating perceived speed changes to the user.

VI. CONCLUSION

The interest in ferrite magnet machines appears to be increasing. As discussed in this study, the ferrite magnet machines are more susceptible to irreversible demagnetization due to armature reaction at lower temperature. Moreover, the ferrite magnet motor performance, especially beyond the constant torque operation varies considerably with magnet temperature. As the temperature of ferrite magnets drops, remanent flux density increases and knee point moves more towards the operating region of magnets in machines. From motor design perspective, as demonstrated in this study, designer has to ensure that the designed ferrite magnet motor is capable of delivering the specified torque throughout the operating speed, without any irreversible demagnetization of magnets.

The temperature dependant characteristics of ferrites have to be considered when designing ferrite magnet machines for applications such as electric powertrain where they are exposed to ambient temperature changes and field weakening operation spans across large operating speeds. This study is carried out on PMBLDC motor and can be extended to other type of ferrite magnet machines also.

ACKNOWLEDGEMENT
