The plasmid-mediated colistin resistance gene, *mcr-1*, was detected in an *Escherichia coli* isolate from a Danish patient with bloodstream infection and in five *E. coli* isolates from imported chicken meat. One isolate from chicken meat belonged to the epidemic spreading sequence type ST131. In addition to IncI2*, an incX4 replicon was found to be linked to *mcr-1*. This report follows a recent detection of *mcr-1* in *E. coli* from animals, food and humans in China.

Very recently, in November 2015, Liu et al. reported the finding of a transferable plasmid-mediated colistin resistance gene, *mcr-1*, detected in *Escherichia coli* isolates from animals, food and patients in China. Moreover, they found *mcr-1* in *Klebsiella pneumoniae* isolates from patients [1]. Horizontal gene transfer represents a paradigm shift in colistin resistance, which until then was thought to be mediated by chromosomal mutations and thus spread by vertical transmission.

National surveillance of antimicrobial resistance in food animals, food and humans in Denmark using whole genome sequencing

Since 2012, the national surveillance of antimicrobial resistance in food animals, food and humans in Denmark (www.DANMAP.org) has used whole-genome sequence (WGS) analysis for detection of resistance genes and multilocus sequence typing (MLST) using the open-access bioinformatic web-tools ResFinder and MLST, respectively from www.genomicepidemiology.org for characterisation of extended spectrum beta-lactamase (ESBL) and AmpC-producing *E. coli* isolates [2-4]. The *mcr-1* sequence from China was added on 24 November 2015 to the ResFinder database as soon as it was available from The National Center for Biotechnology Information (NCBI).

Investigation of presence of *mcr-1* in *E. coli* isolates from food animals, food and human bloodstream infections

The updated version of ResFinder was used to analyse the WGS data from ESBL- and AmpC-producing *E. coli* isolates from food animals and food for the years 2012 to 2014, as well as ESBL- and AmpC-producing *E. coli* isolates from human bloodstream infections, and carbapenemase-producing organisms (CPOs) from humans, from January 2014 to beginning of November 2015 (Table 1), for the presence of *mcr-1*. Furthermore, fluoroquinolone resistance determinants were investigated by searching manually for mutations in the GyrA, ParC and ParE. [5].

The *mcr-1* gene was detected in one *E. coli* isolate from a human bloodstream infection from 2015 and in five *E. coli* isolates obtained from chicken meat of European origin imported to Denmark from 2012, 2013 and 2014 (Table 2). None of the CPOs were positive for *mcr-1* (Table 1).

The patient infected with the *mcr-1*-positive *E. coli* was an elderly man with prostate cancer and repeated urinary tract infections with ESBL-producing *E. coli* resulting in four positive urine samples over five months prior to the bloodstream infection, all resistant to third generation cephalosporins, gentamicin, sulfamethoxazole, trimethoprim and ciprofloxacin (these isolates were not...
investigated further). He had been treated empirically with piperacillin/tazobactam and subsequently meropenem after susceptibility testing of the bloodstream isolate, but not with colistin according to the available patient data.

Besides mcr-1, the human isolate from the Danish patient contained 15 different resistance genes including \( \text{bla}_{\text{CTX-M-55}} \) and \( \text{bla}_{\text{CMY-2}} \) conferring resistance to extended-spectrum beta-lactam antibiotics as well as two GyrA mutations (S83L, D87N) and a ParC mutation (E62K) leading to high-level fluoroquinolone resistance (Table 2). The human mcr-1 positive \( E. \ coli \) isolate belonged to ST744, a rare sequence type in both humans and animals in Denmark. The patient had not been travelling abroad recently and the origin of the isolate is unknown.

The \( \text{bla}_{\text{CMY-2}} \) gene was detected in three of the five mcr-1-positive chicken meat isolates. In addition, three of the chicken meat \( E. \ coli \) isolates carried \( \text{bla}_{\text{SHV-12}} \) conferring resistance to extended-spectrum beta-lactam antibiotics excluding cephamycins.

One of the mcr-1 positive \( E. \ coli \) isolates from chicken meat belonged to ST131. The other chicken meat isolates belonged to sequence types not frequently found in Denmark (Table 2). The human MCR-1-producing \( E. \ coli \) isolate was only susceptible to piperacillin/tazobactam, carbapenems and tigecycline according to the European Committee on Antimicrobial Susceptibility Testing (EUCAST) breakpoints [6], whereas the chicken meat isolates were less resistant (Table 3).

WGS analysis using the web-tool PlasmidFinder [9] identified an IncI2 replicon present in the human isolate as well as in three of the chicken meat isolates, but this replicon was not detected in the remaining two chicken meat isolates. De novo assembly using CLCbio Genomics Workbench (v8.5.1; Qiagen, Aarhus, Denmark) revealed the presence of previously unknown resistance genes in these isolates, thus broadening our understanding of the resistance mechanisms present in Danish meat and human samples.

MLST: multilocus sequence typing; ND: not detected.
Denmark) of the genomic data produced a direct link between the mcr-1 gene and an IncX4 replicon in one of the two isolates not containing IncI2 replicons. An identical IncX4 replicon was detected in four of the chicken meat isolates including both isolates lacking an IncI2 replicon (but not in the human isolate).

### Discussion and conclusion

Here we describe a MCR-1 producing \textit{E. coli} isolate from a human infection coproducing both an ESBL (CTX-M-55) and an AmpC (CMY-2) cephalosporinase as well as five MCR-1 producing \textit{E. coli} from chicken meat coproducing either and ESBL (SHV-12) or an AmpC (CMY-2) cephalosporinase, or both. Human and animal CTX-M-55-producing isolates are commonly reported from Asia \cite{10,11}, but are relatively rarely seen in Denmark. CTX-M-55-producing \textit{E. coli} isolates were detected in only 3\% of the \textit{E. coli} from bloodstream infections in 2014 \cite{4}. CMY-2-producing \textit{E. coli} isolates have commonly been detected from chicken meat both in Denmark and other countries \cite{2-4,12,13}, but \textit{bla}_{CMY-2} has been relatively rare in the Danish human bloodstream \textit{E. coli} isolates. Similarly, only two of the 245 human bloodstream \textit{E. coli} isolates from 2014 were

\footnote{R/I/S according to The Clinical and Laboratory Standards Institute (CLSI) guidelines (M100-S25) \cite{8}.}
SHV-12-producing [4]. Based on antibiogram data it seems plausible that the bloodstream infection is related to the repeated urinary tract infections, but this will need to be confirmed by additional WGS analysis. At this point in time, the origin of the human isolate is unresolved.

MLST analysis did not show any close clonal relationship between any of the six isolates. However, one of the chicken meat isolates belonged to ST131. This sequence type is commonly associated with human E. coli urinary tract and blood infection isolates worldwide, but are rare in animal E. coli isolates [4,14,15]. The fact that a ST131 MCR-1-producing E. coli isolate was found is of special concern, since ST131 isolates have spread epidemically during the last decade [14,15] and the ability of mcr-1 to be acquired by this sequence type has been demonstrated here.

The mcr-1 gene was initially reported to be located on an IncI2 plasmid without other known resistance markers [1]. Here only four of the isolates were found to contain an IncI2 replicon, suggesting that the mcr-1 gene was either located on the chromosome or on a plasmid type belonging to another group. In support of the latter is the fact that de novo assembly of the genomic data from one of the isolates produced a continuous DNA fragment containing both an IncX4 and the mcr-1 gene, strongly suggesting that the mcr-1 gene is not restricted to the IncI2 plasmid group, but additional studies are needed to clarify this further.

In conclusion, this study is to our knowledge, the first proof of colistin-resistant mcr-1 positive E. coli outside China. The human isolate was only susceptible to very few antimicrobial classes such as carbapenems. Should an isolate like this acquire carbapenem resistance, it would leave very few, if any, suitable treatment options. Finally, our findings underline the importance of continuous microbiological surveillance programs and not the least the benefit of employing comprehensive WGS-based surveillance of antimicrobial resistance, as it allows for rapid re-analysis of large datasets in silico and thus make early detection and risk assessment possible when new resistance genes emerge.

Conflict of interest
None declared.

Authors’ contributions
HH and AMH collected the data and drafted the manuscript, HH, MS, PL, EZ and RK did the molecular analysis, FMA, FH, YA, RSH, LC, DSH, BO produced phenotypic data and participated in the coordination and concept of the manuscript, RLS coordinated and edited the manuscript.
