# Stress and strain gradient in the deformed metallic surface

Xiaodan Zhang

Section for Materials Science and Advanced Characterization, Department of Wind Energy, DTU Risø Campus, Roskilde, Denmark

Vintermødet 2016, 20-22 Jan, 2016, Viborg

#### Surface deformation introduces gradient structure

A gradient structure produced by surface plastic deformation with characteristics:

- Limited extension of the deformed surface layer to a depth of several mms to ~ 1 mm;
- Structural scale from nanometers to tens of micrometers increasing with increasing distance from the surface;
- Increasing strength with increasing structural fineness.

Other factors: residual stresses, chemical effects, surface morphology and roughness.

How to evaluate the stress and strain from the surface deformation microstructure ?

Vintermødet 2016, 20-22 Jan, 2016, Viborg

#### Gradient nanostructures - processing

- Shot peening;
- Surface mechanical attrition (SMAT);
- Deep rolling;
- Surface mechanical grinding (SMGT);
- Friction and sliding;
- Wear.

|                      | Shot-peening                       | SMAT                                 |
|----------------------|------------------------------------|--------------------------------------|
| Shot size            | 0.05 ~ 1 mm                        | 1 ~ 10 mm                            |
| Shot velocity        | ~ 100 m/s                          | 1 ~20 m/s                            |
| Shot direction       | Single direction (~ $90^{\circ}$ ) | Multi-direction                      |
|                      |                                    | (vibration frequency: 20 ~ 50<br>HZ) |
| Temperature increase | 50-100 °C                          | 50-100 °C                            |
| Thickness of graded  | ~ 100 µm – 1 mm                    | ~ 40 µm – 1 mm                       |
| nanostructures       |                                    |                                      |

## Shot Peening (1)

Analyze graded deformation structure by comparing with layered cold-rolled structure.

0.8 mm high-carbon steel balls High shot velocity: 260-300 m/s

Cold rolling: low to high strain Strain rate: about 0.3 s<sup>-1</sup>

Material Pure industrial iron: Fe-0.004C-0.44Al-0.017Ni-0.13Mn-0.0066P

### Shot-peening (2)

#### **Distance from surface**

- **b)** 1200 600  $\mu$ m from surface
- c) 460 260  $\mu$ m from surface
- d) 260 60  $\mu$ m from surface
- e) 60 30 μm from surface
  - **f)** 30 0  $\mu$ m from surface

 $\boldsymbol{b}{:}~1200$  -  $600~\mu m$  from surface

Inner

surface

7

Black line: high angle boundary (Misorientation angle >  $15^{\circ}$ )

### Shot-peening (3)

**c**: 460 - 260 µm from surface

d: 260 - 60  $\mu$ m from surface

Inner

surface

8

#### Shot-peening (4)

 $\boldsymbol{e} {:}~60$  - 30  $\mu m$  from surface

f: 30 - 0  $\mu m$  from surface

Inner

9

### Shot-peening (5) Typical deformation structure LAB/HAB

Lamellar boundary misorientation angle (EBSD)

60 - 40  $\mu m$  from surface

40 - 20  $\mu$ m from surface 20 - 10  $\mu$ m from surface 10 - 0  $\mu$ m from surface  $^{\circ}$ 

#### Shot-peening (6)

## Shot-peening (7)

Vickers Hardness up to 25  $\mu$ m from surface. The top layer with the finest structure cannot be analyzed with good precision.

Relationships between microstructural parameters and the stress and strain state in a gradient structure

## Direct estimate of stress and strain distributions in a gradient structure

• Stress estimate: microhardness, nanoindentation, miniature test samples.

• Strain estimate: displacement of structural markers as grain boundaries, twin boundaries and embedded pins, neutron diffraction and high energy synchrotron X-rays.

# Indirect estimate of stress and strain distribution in a gradient structure

The layered structures in shot-peened, and coldrolled samples have similar characteristics and it is suggested to use the structure-property relationships for rolled (bulk) samples as a baseline for the analysis of shot-peened samples.

# Flow stress ( $\sigma$ ) as a function of boundary spacing ( $D_{av}^{-0.5}$ )

# Stress distribution in the gradient surface structure of a shot peened sample

#### Conclusions

- In medium to high stacking fault energy fcc and bcc metals, the analysis of deformed layered microstructures reveals that dislocation processes dominate from the macroscale to a limit of 5 nm, which may be reduced further.
- A gradient layered structure can be produced by surface plastic deformation reducing the structural scale to the nanometer dimension and increasing the strength to extreme values by dislocation and boundary strengthening. Structural evolution and strengthening mechanisms are promising research areas.
- Computational and materials modelling must be advanced from bulk to gradient structures. Goals are by model integration and validation to optimize processing conditions and properties (e.g. wear and fatigue) of industrial component (e.g. gears and bearings in wind generators).
- Gradient nanostructures are an important addition to the global field of nanoscience and technology.

### **Applications**

#### Wind energy

Gears

Bearings

Crankshafts

### Applications

Rails

#### Wind energy

Implants
