Abstract

Regularized Green's functions for mixed unbounded-periodic domains are derived. The regularization of the Green's function removes its singularity by introducing a regularization radius which is related to the discretization length and hence imposes a minimum resolved scale. In this way the regularized unbounded-periodic Green's functions can be implemented in an FFT-based Poisson solver to obtain a convergence rate corresponding to the regularization order of the Green's function. The high order is achieved without any additional computational cost from the conventional FFT-based Poisson solver and enables the calculation of the derivative of the solution to the same high order by direct spectral differentiation. We illustrate an application of the FFT-based Poisson solver by using it with a vortex particle mesh method for the approximation of incompressible flow for a problem with a single periodic and two unbounded directions.

Keywords: The Poisson equation, unbounded and periodic domains, mixed boundary conditions, regularization methods, Green's function solution, Vortex methods

1. Introduction

The Poisson equation is an elliptic equation that most commonly appear in physics when solving potential fields. Examples are the potential of gravitational or electrical charge interactions, or the velocity field induced by a vortex in a potential flow. In this work we propose a high order solver for the Poisson equation for mixed unbounded-periodic domains, which are domains having a mixture of unbounded and periodic directions based on a Green's function approach. In terms of boundary conditions we may use the phrase mixed periodic and free-space boundary conditions.

Using Green's functions is the preferred method for solving linear differential equations in an unbounded domain. The Green's function represents a homogeneous solution which is derived analytically with the appropriate boundary conditions, and then used to obtain the particular solution by a convolution with the right-hand-side field of the Poisson equation.

For triple periodic systems it is widely used within the field of electrostatics to decompose the electrostatic potential into a singular short-range term and a smooth long-range term. This technique is known as Ewald summation [1]. It constitutes an N -body problem, where N is the number of charged particles contained within the unit domain. The summation may be calculated using particle-particle particle-mesh like methods [2], where the long-range term is computed in Fourier space using an FFT-based particle-mesh method with computational efforts scaling $\mathcal{O}(N \log N)$ (see e.g., [3, 4]). Likewise, expressions for the Ewald sums for the cases of mixed periodic and free-space boundary conditions have been derived in [5] also applicable for fast summation methods [6, 7]. The Ewald summation technique, however does not provide an explicit Green's function, which may be discretized and used with a generic solution procedure such as the FFT-based solver presented in the following.

A high-order FFT solver for the unbounded Poisson equation has recently been presented in references [8, 9, 10]. Here the high order is achieved by deriving regularized Green's functions by removing its singularity through the introduction of a minimum resolved length scale. The method is based on the work of references [11, 12, 13, 14, 15] who employ regularized particles for mesh free particle interactions. We note that solvers based on the adaptive Fast Multipole Method (FMM) [16, 17] are alternatives to the FFT-based solvers. The FMM based solvers have an advantage in systems with highly non-uniform particle distributions, since they are not restricted to uniform meshes (see [18] for a detailed comparison of computational efforts required for the two methods). For details on higher-order FMM methods for partial differential equations in general the reader is referred to the references [19, 20].

A simple approach to obtain a Green's function for unbounded-periodic domains is to use the method of repeating domains where the unbounded Green's function is summed to implicitly account for a specified number of repeated fields and thus obtain a semi-periodic solution [21]. With the FMM this is effectively employed, since only a local multipole expansion of the unit domain need to be summed to account for the well-separated repeated domains with insignificant additional computational efforts [16]. For a mesh-based FFT-solver however, the method impose a growth of the efforts associated with the precomputation of the convolution kernel, that scales linearly with the number of repeated domains. In both cases it introduces an additional parameter in the algorithm which influences the overall accuracy of the method. The high order regularized Green's functions for unbounded domains derived in references [8, 9, 10] may be used together with the method of repeating domains. For this approach the error due to the semi-periodic approximation convergences with respect to the number of repeated domains as first and third order in two- and three dimensions (2D and 3D), respectively [10]. This corresponds to the rate of decay of the free-space Green's functions in the two spatial dimensions. Hence it may be well worth to look for analytic Green's functions which implicitly account for the periodicity.

A more formal approach to achieve a Green's function for unbounded-periodic domains was proposed by Chatelain and Koumoutsakos [22]. Here the Poisson equation was solved directly in the periodic directions

yielding a modified Helmholtz equation for the unbounded directions which in turn is solved by deriving the appropriate real space Green's functions.

In the present work we adopt the approach of Chatelain and Koumoutsakos [22] by deriving Green's functions which are functions of Fourier space variables in the periodic directions and real space variables in the unbounded directions. Combined with the regularization method presented in [8, 9, 10] we derive regularized Green's functions for unbounded-periodic domains. The regularized unbounded-periodic Green's functions are implemented in an FFT-based Poisson solver using the zero-padding method of Hockney and Eastwood [2] to obtain a linear convolution in the unbounded directions. We show that the solver obtains a convergence rate corresponding to the regularization order of the Green's function.

For a single free-space and one or more periodic boundary conditions, we note that solving the Poisson equation essentially reduces to solving a one-dimensional modified Helmholtz equation with free-space boundary conditions for each wave number set (when having Fourier transformed the problem in the periodic directions). A spectrally accurate procedure for doing this has been outlined in [23, 24]. This procedure is not applicable when the system has more than one free-space condition.

2. Methodology

The Poisson equation is formally stated as

$$\nabla^2 A(\mathbf{x}) = -B(\mathbf{x}), \quad (1)$$

where $B(\mathbf{x})$ is a known bounded field and $A(\mathbf{x})$ is the desired solution field. As $B(\mathbf{x})$ is bounded we may state for the unbounded domains, that

$$A(\mathbf{x}) \rightarrow 0 \quad \text{for} \quad |\mathbf{x}| \rightarrow \infty \quad (2)$$

and for the periodic domains that

$$A(\mathbf{x}) = A(\mathbf{x} + n\mathbf{L}). \quad (3)$$

Here $\mathbf{L}$ is the length of the domain and $n \in \mathbb{Z}$. In this work we seek the solution of Eq. (1) for an unbounded-periodic domain which is subject to the conditions of Eqs. (2) and (3) for the unbounded and periodic directions, respectively.

In many applications such as astrophysics, electrodynamics and vortex dynamics, the vector field to be solved $\mathbf{v}(\mathbf{x})$ is described by potential functions using the Helmholtz decomposition

$$\mathbf{v}(\mathbf{x}) = \nabla \times \boldsymbol{\psi}(\mathbf{x}) - \nabla \phi(\mathbf{x}) \quad \text{where} \quad \nabla \cdot \boldsymbol{\psi}(\mathbf{x}) = 0. \quad (4)$$

The fundamental operations describing the conservation of the flux and circulation of the vector field $\mathbf{v}$ is the divergence $\vartheta(\mathbf{x}) = \nabla \cdot \mathbf{v}(\mathbf{x})$ and the curl $\boldsymbol{\omega}(\mathbf{x}) = \nabla \times \mathbf{v}(\mathbf{x})$, respectively. From Eq. (4) it follows that

these may be expressed by the potential functions as

$$\vartheta(\mathbf{x}) = -\nabla^2 \phi(\mathbf{x}) \quad \text{and} \quad \omega(\mathbf{x}) = -\nabla^2 \psi(\mathbf{x}). \quad (5)$$

As seen, both potentials may be obtained by solving the Poisson equation. By utilizing the linearity of the Poisson equation and considering the equations by their Fourier transform we obtain the algebraic equations

$$\begin{aligned} -k^2 \hat{\phi}(\mathbf{k}) &= -\hat{\vartheta}(\mathbf{k}) & \hat{\phi}(\mathbf{k}) &= \hat{G}(\mathbf{k}) \hat{\vartheta}(\mathbf{k}) \\ -k^2 \hat{\psi}(\mathbf{k}) &= -\hat{\omega}(\mathbf{k}) & \hat{\psi}(\mathbf{k}) &= \hat{G}(\mathbf{k}) \hat{\omega}(\mathbf{k}) \end{aligned} \quad \Rightarrow \quad \text{where} \quad \hat{G}(\mathbf{k}) = \frac{1}{k^2}. \quad (6)$$

Here $\hat{\cdot}$ denotes a Fourier transformed variable, ι the imaginary unit, $\mathbf{k}$ is the angular wave-number of the Fourier space, and $k = |\mathbf{k}|$ its modulus. $\hat{G}(\mathbf{k})$ is the Green's function in Fourier space which represents the homogeneous solution to the Poisson equation. We may furthermore obtain the vector field of Eq. (4) directly by incorporating the gradient operator into the Green's function as $\mathbf{K}(\mathbf{x}) = \nabla G(\mathbf{x})$ after which

$$\begin{aligned} -k^2 \hat{\mathbf{v}}_{\vartheta}(\mathbf{k}) &= -\iota \mathbf{k} \hat{\vartheta}(\mathbf{k}) & \hat{\mathbf{v}}_{\vartheta}(\mathbf{k}) &= \hat{\mathbf{K}}(\mathbf{k}) \hat{\vartheta}(\mathbf{k}) \\ -k^2 \hat{\mathbf{v}}_{\omega}(\mathbf{k}) &= -\iota \mathbf{k} \times \hat{\omega}(\mathbf{k}) & \hat{\mathbf{v}}_{\omega}(\mathbf{k}) &= \hat{\mathbf{K}}(\mathbf{k}) \times \hat{\omega}(\mathbf{k}) \end{aligned} \quad \Rightarrow \quad \text{where} \quad \hat{\mathbf{K}}(\mathbf{k}) = \frac{\iota \mathbf{k}}{k^2}. \quad (7)$$

It is seen that the solution to the Poisson equations in Eqs. (6) and (7) is obtained by means of a convolution between the Green's function and the right-hand-side of the Poisson equation. The linear convolution needed in the unbounded directions is achieved by the zero-padding method of Hockney and Eastwood [2].

The real space Green's function is obtained by the inverse Fourier transform using the appropriate integration intervals for each direction i.e. an unbounded interval for the unbounded directions and a periodic interval for the periodic directions. However, for a discrete approximation, such as is used in numerical simulations, the discretization of the domain in the physical space, results in a bounded domain in the Fourier space, represented by the set of wave-numbers $k_i = -k_s/2, \dots, k_s/2$. Here $k_s = 2\pi/h$ is the angular sampling wave-number corresponding to the discretization length h and $k_s/2$ is the highest resolved angular wave-number due to the Nyquist-Shannon sampling theorem. The exact Green's function of Eq. (6) can thus not be represented in a discretized space and using it will introduce errors in the calculation with a limited convergence rate of $\mathcal{O}(h^2)$ cf. Rasmussen [25].

In order to amend this and derive a method to achieve a higher order convergence rate is to use a spectrally compact regularization function which makes the integral of the inverse Fourier transform convergent within its integration interval. Hence the regularization function should to be chosen to fulfill

$$\hat{\zeta}(k) = 1 \quad \text{for} \quad k = 0 \quad \text{and} \quad \hat{\zeta}(k) = 0 \quad \text{for} \quad k \geq k_s/2 \quad (8)$$

This leads to a regularized Green's function which is bounded by a maximum wavenumber and the corre-

114 sponding homogeneous equation becomes

$$\widehat{G}(k) = \frac{\widehat{\zeta}(k)}{k^2} \Rightarrow \nabla^2 G(r) = -\zeta(r). \quad (9)$$

115 The order of the regularization function is increased to m -th order by nullifying the $m-2$ order derivatives
116 of the spectral function at $k=0$. This is equivalent to conserving the higher order moments in real space
117 which is summarized by the following additional requirements

$$\left. \frac{d^\beta \widehat{\zeta}}{dk^\beta} \right|_{k=0} = \int_{-\infty}^{\infty} r^\beta \zeta(r) d\mathbf{x} = 0^\beta \quad \text{for } \beta = 0, 2, \dots, m-2. \quad (10)$$

118 We note that m is an even number and that the moments for odd integers of β are automatically satisfied
119 due to the radial symmetry of the function.

120 Following Hejlesen et al. [8, 9, 10] we obtain a high order regularization function ζ_m of order m by
121 performing an approximate deconvolution which effectively conserves higher order moments of the original
122 field. A high order Gaussian regularization function can thus be obtained from a Gaussian function by

$$\widehat{\zeta}_m(s) = \widehat{D}_m(s) \exp\left(-\frac{s^2}{2}\right) \quad \text{where} \quad \widehat{D}_m(s) = \sum_{n=0}^{m/2-1} \frac{(s^2/2)^n}{n!}. \quad (11)$$

123 Here $s = k\sigma$ is the radial angular wave-number normalized with σ , which represents a smoothing radius.
124 $\widehat{D}_m$ is an m -th order approximation of the inverse Gaussian function.

125 As k_s is proportional to $1/h$, and the extent of the Gaussian regularization function in Fourier space is
126 proportional to $1/\sigma$ the formal choice of smoothing radius is $\sigma = \alpha h$ where $\alpha = 2$. In this way the bounds of
127 the Fourier space (i.e. $k_s/2$) and the extent of the Gaussian regularization function scales equally, resulting
128 in a constant truncation error when varying h .

129 We now derive the regularized Green's functions for the Poisson equation in a mixed periodic and un-
130 bounded domain in 2D, and then extend the result to the 3D case with two periodic and one unbounded
131 direction. In 2D with one periodic (the y -direction) and one unbounded (the x -direction) boundary condi-
132 tions, the regularized Green's function is found by the inverse Fourier transform

$$G_m(x, y) = \frac{1}{2\pi} \int_{-k_s/2}^{k_s/2} \left(\frac{1}{2\pi} \int_{-\infty}^{\infty} \frac{\widehat{\zeta}_m(\sqrt{k_x^2 + k_y^2})}{k_x^2 + k_y^2} \exp(\iota k_x x) dk_x \right) \exp(\iota k_y y) dk_y. \quad (12)$$

133 For the Green's function which has been Fourier transformed in the y -direction and using normalized coor-
134 dinates, we have

$$\widehat{G}_m(\rho_x, s_y) = \frac{\sigma}{2\pi} \int_{-\infty}^{\infty} \frac{\widehat{\zeta}_m(\sqrt{s_x^2 + s_y^2})}{s_x^2 + s_y^2} \exp(\iota s_x \rho_x) ds_x, \quad (13)$$

135 where $s_x = \sigma k_x$, $s_y = \sigma k_y$, and $\rho_x = |x|/\sigma$. Inserting the Gaussian regularization function on the generic
136 form (Eq. (11)) we obtain

$$\widehat{G}_m(\rho_x, s_y) = \frac{\sigma}{2\pi} \exp\left(-\frac{\rho_x^2 + s_y^2}{2}\right) \int_{-\infty}^{\infty} \frac{D_m(\sqrt{s_x^2 + s_y^2})}{s_x^2 + s_y^2} \exp\left(-\frac{(s_x - \iota \rho_x)^2}{2}\right) ds_x. \quad (14)$$

By changing to radial variables and using integration by parts this integral may be found on the general form

$$\begin{aligned}\hat{G}_m(\rho, s) = & \frac{\sigma}{4s} \left[\left(1 - \operatorname{erf} \left(\frac{s-\rho}{\sqrt{2}} \right) \right) \exp(-s\rho) + \left(1 - \operatorname{erf} \left(\frac{s+\rho}{\sqrt{2}} \right) \right) \exp(s\rho) \right] \\ & + \frac{\sigma\sqrt{2}}{\sqrt{\pi}} P_m(s, \rho) \exp\left(-\frac{s^2+\rho^2}{2}\right).\end{aligned}\quad (15)$$

Here $P_m(s, \rho)$ is a polynomial which for $m = \{2, 4, 6, 8, 10\}$ is given by

$$\begin{aligned}P_2(s, \rho) &= 0 & P_8(s, \rho) &= \frac{11}{32} + \frac{1}{12}s^2 - \frac{1}{8}\rho^2 - \frac{1}{48}s^2\rho^2 + \frac{1}{96}(s^4 + \rho^4) \\ P_4(s, \rho) &= \frac{1}{4} & P_{10}(s, \rho) &= \frac{93}{256} + \frac{73}{768}s^2 - \frac{47}{256}\rho^2 - \frac{17}{384}s^2\rho^2 + \frac{11}{768}s^4 \\ P_6(s, \rho) &= \frac{5}{16} + \frac{1}{16}(s^2 - \rho^2) & & + \frac{23}{768}\rho^4 + \frac{1}{256}(s^2\rho^4 - s^4\rho^2) + \frac{1}{768}(s^6 - \rho^6).\end{aligned}\quad (16)$$

137 Extending the results to the 3D case we may define the radial variables as

$$s = \begin{cases} |s_y| & \text{for 2D} \\ \sqrt{s_y^2 + s_z^2} & \text{for 3D} \end{cases} \quad \text{and} \quad \rho = \begin{cases} |\rho_x| & \text{for 2D} \\ |\rho_x| & \text{for 3D} \end{cases} \quad (17)$$

138 For the case of $s = 0$ we may define the Green's function arbitrarily as it represents the average value of the
139 solution which for a potential is arbitrarily defined. In this work we have used $\hat{G}_m(\rho, 0) = 0$. We furthermore
140 notice that for $\sigma \rightarrow 0$ the regularized Green's function (Eq. (15)) reduces to the non-regularized Green's
141 function obtained by Chatelain and Koumoutsakos [22].

142 The regularized Green's function for the Poisson equation in 3D for the case with one periodic (z) and
143 two unbounded directions (x and y) may be derived following the approach above. The Fourier transform
144 of the Green's function in the periodic z -direction is the 2D radial inverse Fourier transform

$$\hat{G}_m(\rho, s_z) = \frac{1}{2\pi} \int_0^\infty \frac{\hat{\zeta}_m(\sqrt{s^2 + s_z^2})}{s^2 + s_z^2} J_0(s\rho) s \, ds, \quad (18)$$

145 where $s^2 = s_x^2 + s_y^2$ and $\rho^2 = \rho_x^2 + \rho_y^2$.

146 It is however not trivial to find a closed form expression of the integral Eq. (18), but we notice that to
147 compute discrete solutions to Eq. (5) using the FFT-based Poisson solver a regular spectral representation is
148 sufficient. The integrand of Eq. (18) is regular for $s_z^2 \neq 0$ and may be used as it is stated. For $s_z^2 = 0$ it may
149 be expressed through the completely unbounded regularised Green's function in 2D proposed by Hejlesen
150 et al. [8]

$$\hat{G}_m(s, s_z) = \begin{cases} \hat{G}_m^{2D}(s) \frac{D_m(\sqrt{s^2 + s_z^2})}{D_m(\sqrt{s^2})} \exp\left(-\frac{s_z^2}{2}\right) & \text{for } s_z = 0 \\ \frac{\hat{\zeta}_m(\sqrt{s^2 + s_z^2})}{s^2 + s_z^2} & \text{for } s_z \neq 0 \end{cases} \quad (19)$$

$$G_m^{2D}(\rho) = -\frac{1}{2\pi} \left(\ln(\sigma\rho) - Q_m(\rho) \exp\left(-\frac{\rho^2}{2}\right) + \frac{1}{2} E_1\left(\frac{\rho^2}{2}\right) \right), \quad (20)$$

where $\hat{G}_m^{2D}(s)$ is the 2D radial Fourier transform of $G_m^{2D}(\rho)$ and $Q_m(\rho)$ is a polynomial given in [8]

$$\begin{aligned} Q_2(\rho) &= 1 & Q_6(\rho) &= 1 - \rho^2 + \frac{1}{8}\rho^4 \\ Q_4(\rho) &= 1 - \frac{1}{2}\rho^2 & Q_8(\rho) &= 1 - \frac{3}{2}\rho^2 + \frac{3}{8}\rho^4 - \frac{1}{48}\rho^6 \\ & & Q_{10}(\rho) &= 1 - 2\rho^2 + \frac{3}{4}\rho^4 - \frac{1}{12}\rho^6 + \frac{1}{384}\rho^8. \end{aligned} \quad (21)$$

The Fourier coefficients of Eq. (19) may in principle be computed faster than those of [22] as the computation involves the FFT of a single plane only, but in a parallel implementation, it may be difficult to exploit this. The method however may be used with the spectral accurate 2D unbounded kernels by [10, 26] or [27]. The kernel by [27] is conveniently given in Fourier-space but it impose a zero-padding in a precomputation step by a length in each direction greater than or equal to the maximum distance between any two particles in the computational domain. Hence may not be feasible for aspect ratios larger than one.

3. Results

3.1. Verification of accuracy

To investigate the accurate and consistency of the FFT-based Poisson solver with mixed boundary conditions, we must consider a test function that is bounded within the computational domain in the unbounded directions, and fully continuously differentiable in the periodic directions. The test function must furthermore have at least two continuous derivatives which is a direct consequence of the mapping of the Laplace operator $\nabla^2 : C^m \rightarrow C^{m-2}$ after which $m \geq 2$ is needed to give a continuous solution for the Poisson equation. However, in order to make the quadrature error insignificant and thus allowing an arbitrary high convergence rate the test function must be infinitely differentiable.

To meet these requirements we use a sine function for the periodic directions and a normalized bump function distribution in the unbounded directions, which both are of class C^∞ i.e. it has an infinite number of continuous derivatives. The bump function is defined as

$$f(q) = \begin{cases} \exp \left[c \left(1 - \frac{1}{1-q^2} \right) \right] & \text{for } |q| < 1 \\ 0 & \text{for } |q| \geq 1, \end{cases} \quad (22)$$

where c is an arbitrary positive constant. For the presented cases $c = 10$ is used.

For the 2D case with one unbounded (x) and one periodic (y) directions, we solve the scalar equation of Eq. (5) using the test function solution

$$\phi(x, y) = f\left(\frac{x}{R}\right) \sin(2\pi y). \quad (23)$$

172 Similarly, for the 3D case with one unbounded (x) and two periodic (y and z) directions, we use the test
173 function solution

$$\phi(x, y, z) = f\left(\frac{x}{R}\right) \sin(2\pi y) \sin(2\pi z). \quad (24)$$

174 For the 3D case with two unbounded (x and y) and one periodic (z) directions, we use a test func-
175 tion solution which is non-zero when averaged in the periodic direction to verify a consistent treatment of
176 singularity at $s_z = 0$

$$\phi(x, y, z) = f\left(\frac{\sqrt{x^2 + y^2}}{R}\right) [1 + \sin(2\pi z)]. \quad (25)$$

177 We solve the scalar equation and define the error of the calculated vector field ϑ_i compared to the analytic
178 solution which is sampled in the same points $\vartheta(\mathbf{x}_i)$ as

$$\text{error} = \left(\sum_{i=1}^N |\vartheta(\mathbf{x}_i) - \vartheta_i|^2 / \sum_{i=1}^N |\vartheta(\mathbf{x}_i)|^2 \right)^{1/2}. \quad (26)$$

179 The obtained error for the regularized Poisson solver with mixed boundary conditions is shown in Fig. 1
180 compared to the non-regularized method of Chatelain and Koumoutsakos [22] in 3D for a single periodic
181 direction.

182 Also we compare to results obtained by point to point evaluations of the analytic Green's function for
183 the 2D problem by Lamb [28, 29] written in complex notation as:

$$G(\mathbf{x}) = -\frac{1}{2\pi} \log \left(\sin \frac{\pi(z)}{L} \right), \quad z = x + iy. \quad (27)$$

184 It is seen that the method obtains the convergence rate corresponding to the respective design parameters
185 of the Green's functions. The regularized method is shown to quickly produce an error which is significantly
186 lower than that of [22] and [28, 29] in the 2D case for $m > 2$. Similarly the regularized method shows lower
187 error in 3D for all tested resolutions for $m > 2$. Using $m = 10$ gives an improvement in accuracy by several
188 orders from the coarsest resolution.

189 3.2. Instability of counter rotating vortex pairs

190 We illustrate an application of the FFT-based Poisson solver for a problem with mixed boundary condi-
191 tions (two unbounded and one periodic direction) by simulating the evolution of two counter rotating vortex
192 pairs from an initial state following [30, 31, 22].

193 The vorticity transport equation, which governs incompressible fluid motion is given by

$$\frac{D\boldsymbol{\omega}}{Dt} = (\boldsymbol{\omega} \cdot \nabla) \mathbf{v} + \nu \nabla^2 \boldsymbol{\omega}, \quad (28)$$

194 where $\boldsymbol{\omega} = \nabla \times \mathbf{v}$. Eq. (28) is discretized using a vortex particle mesh method; the vorticity ($\boldsymbol{\omega}$) is sampled
195 onto a set of discrete particles carrying vorticity ($\boldsymbol{\omega}_p$). The particle vorticity is interpolated to a uniform

Figure 1: The error of the calculated solutions obtained by the m -th order regularized Green's functions: (a) 2D problem with one unbounded and one periodic direction; (b) 3D problem with one unbounded and two periodic directions. (c) 3D problem with two unbounded and one periodic direction. Lines indicate: convergence order (---) from top $\mathcal{O}(h^2)$, $\mathcal{O}(h^4)$, $\mathcal{O}(h^6)$, $\mathcal{O}(h^8)$, $\mathcal{O}(h^{10})$; point to point evaluation with the Green's function by Lamb [28, 29]: ($\times$); the non-regularized Green's function [22]: (—); $m = 2$: ($\circ$); $m = 4$: ($\square$); $m = 6$: ($+$); $m = 8$: ($\diamond$); $m = 10$: ($\triangle$).

196 grid using a third order accurate interpolation kernel [32]. We use the FFT-based Poisson solver to compute
 197 the velocity ($\mathbf{v}$) by applying the Helmholtz decomposition to the velocity as Eq. (4) and solve for the vector
 198 potential in Eq. (5) followed by a spectral approximation to the curl. For the Poisson solver we use a tenth
 199 order accurate Green's function with $\alpha = 2$. The discrete approximation is evolved in the Lagrangian frame
 200 of reference by applying a second order explicit Runge-Kutta time stepping scheme to

$$\frac{d\mathbf{x}_p}{dt} = \mathbf{v}(\mathbf{x}_p, t) \quad (29)$$

$$\frac{d\boldsymbol{\omega}_p}{dt} = [(\boldsymbol{\omega} \cdot \nabla)\mathbf{v} + \nu \nabla^2 \boldsymbol{\omega}]_p. \quad (30)$$

201 Further we enforce a divergence free vorticity field when necessary through a projection step based on
 202 the Helmholtz decomposition (Eq. (4)). This is done whenever a norm of the vorticity divergence exceeds a
 203 certain threshold, which happens every few steps in the current example (for the details see [33]).

204 The initial vorticity field consists of two counter rotating vortex-pairs given as

$$\boldsymbol{\omega} = \sum_i \frac{\Gamma_i}{\pi} \left(\frac{\phi}{p_i^2 + \phi^2} \right)^2 \mathbf{e}_z - \sum_i \frac{\Gamma_i}{\pi} \left(\frac{\phi}{q_i^2 + \phi^2} \right)^2 \mathbf{e}_z, \quad (31)$$

$$p_i^2 = (x + b_i)^2 + (y - \epsilon)^2, \quad q_i^2 = (x - b_i)^2 + (y - \epsilon)^2, \quad (32)$$

205 where z is the periodic direction and p_i, q_i are the perturbed radii of the respective vortices in the unbounded
 206 plane. Following [30, 31, 22] we use $\Gamma_2/\Gamma_1 = -0.3$, $b_2/b_1 = 0.3$, $\phi_1/b_1 = 0.075$ and $\phi_2/b_1 = 0.05$ and
 207 define the timescale and the Reynolds number based on the initial circulation ($\Gamma_0 = \Gamma_1 + \Gamma_2$) and centroid
 208 ($b_0 = [\Gamma_1 b_1 + \Gamma_2 b_2]/\Gamma_0$)

$$T = 2\pi b_0^2/\Gamma_0, \quad \text{Re} = \Gamma_0/\nu = 3500. \quad (33)$$

209 The system is primarily unstable to the mode of wave length $\lambda_z/b_0 = 0.76$ [30, 31]. To onset the instability
 210 the perturbation is set as $\epsilon(z) = 10^{-5} b_0 \sin(2\pi z/\lambda_z)$. The computational domain spans a single wave length
 211 of this mode in the periodic direction ($L_z = \lambda_z$) and the span in the unbounded directions is adapted to
 212 encapsulate vortex particles for which $|\boldsymbol{\omega}_p| > 10^{-4} |\boldsymbol{\omega}|_{\max}$.

213 We measure the time variation of the enstrophy (Ω) and the distribution of kinetic energy among wave
 214 numbers ($E(k_z)$)

$$\Omega = \int \boldsymbol{\omega}(x, y, z) \cdot \boldsymbol{\omega}(x, y, z) dV \quad (34)$$

$$E(k_z) = \int \int \frac{1}{2} \left(\hat{\Psi}^*(x, y, k_z) \cdot \hat{\boldsymbol{\omega}}(x, y, k_z) + \hat{\boldsymbol{\omega}}^*(x, y, k_z) \cdot \hat{\Psi}(x, y, k_z) \right) dx dy, \quad (35)$$

215 where $(\cdot)^*$ denotes the complex conjugate.

216 The evolution of enstrophy is shown in Fig. 2(a). It may be seen that that the obtained results converge
 217 (with mesh refinement) towards the same solution as obtained in [22] (for $h/L_z = 256$). Furthermore the

Figure 2: (a) Evolution of enstrophy. (b) Evolution of kinetic energy associated with first three modes: 0th: (solid); 1st: (dashed); 2nd: (dotted). Line colors indicate results from: [22]: (—); simulation using $h/L_z = 64$: (—); simulation using $h/L_z = 128$: (—); simulation using $h/L_z = 256$: (—).

time history of kinetic energy associated with first three modes (Fig. 2(b)) displays very similar growth rates as in [22] though the current results are slightly delayed possible due different perturbation applied or other variations in the algorithms (e.g., time stepping and projection-scheme). Iso contours of the vorticity magnitude is shown for different time instances in Fig. 3. These shows a transition from a 2D state into a 3D state primarily through the perturbed wave length. The 3D dynamic involves a stretching of one pair member around the other and creation of smaller scales in the solution through non-linear interaction.

4. Conclusion

Regularized Green's functions for domains with a mixture of unbounded and periodic directions has been derived. The regularization of the Green's function removes its singularity by introducing a regularization radius which is related to the discretization length and hence imposes a minimum resolved scale. The regularized unbounded-periodic Green's functions has been implemented in a high order FFT-based Poisson solver for domains with a mixture of unbounded and periodic directions. The Poisson solver has been shown to results in a convergence rate corresponding to the regularization order of the Green's function and its applicability has been demonstrated in a vortex particle mesh method. The high order is achieved without any additional computational cost from the conventional FFT-based Poisson solver and is able to calculate the derivative of the solution to the same high order by direct spectral differentiating.

Acknowledgement

We would like to acknowledge the helpful discussions with Johannes Tophøj Rasmussen, Philippe Chate-lain and Grégoire Winckelmans. Further, we thank the reviewers for their insightful and helpful comments.
