Abstract Submitted
for the MAR17 Meeting of
The American Physical Society

How to measure separations and angles between intra-molecular fluorescent markers¹ HENRIK FLYVBJERG, KIM I. MORTENSEN, Tech Univ of Denmark, JONGMIN SUNG², Dept of Biochem and Dept of Phys, Stanford University, JAMES A. SPUDICH, Dept of Biochem, Stanford University School of Medicine — We demonstrate a novel, yet simple tool for the study of structure and function of biomolecules by extending two-colour co-localization microscopy to fluorescent molecules with fixed orientations and in intra-molecular proximity. From each color-separated microscope image in a time-lapse movie and using only simple means, we simultaneously determine both the relative (x,y)-separation of the fluorophores and their individual orientations in space with accuracy and precision. The positions and orientations of two domains of the same molecule are thus time-resolved. Using short double-stranded DNA molecules internally labelled with two fixed fluorophores, we demonstrate the accuracy and precision of our method using the known structure of double-stranded DNA as a benchmark, resolve 10-base-pair differences in fluorophore separations, and determine the unique 3D orientation of each DNA molecule, thereby establishing short, double-labelled DNA molecules as probes of 3D orientation of anything to which one can attach them firmly.
