11 Abstract

The study is part 2 of 2 in an investigation of gasification and co-gasification of municipal sewage sludge in low 12 13 temperature gasifiers. In this work, solid residuals from thermal gasification and co-gasification of municipal 14 sewage sludge were investigated for their potential use as fertilizer. Ashes from five different Low Temperature 15 Circulating Fluidized Bed (LT-CFB) gasification campaigns including two mono-sludge campaigns, two 16 sludge/straw mixed fuels campaigns and a straw reference campaign were compared. Experiments were 17 conducted on two different LT-CFBs with thermal capacities of 100 kW and 6 MW, respectively. The 18 assessment included: i) Elemental composition and recovery of key elements and heavy metals; ii) content of 19 total carbon (C) and total nitrogen (N); iii) pH; iv) water extractability of phosphorus after incubation in soil; and 20 v) plant phosphorus response measured in a pot experiment with the most promising ash material. The results 21 showed that co-gasification of straw and sludge in LT-CFB gasifiers gave the best fertilizer qualities across all 22 assessed characteristics. These mixed fuel gasification ashes had a high content of recalcitrant C, phosphorus 23 (P) and potassium (K), a low content of heavy metals (especially cadmium) and an improved plant P availability 24 compared to the mono-sludge ashes. It was also found that bottom ashes from the char reactor contained 25 even less heavy metals than cyclone ashes. It is concluded that LT-CFB gasification and co-gasification is a 26 highly effective way to purify and sanitize sewage sludge for subsequent use in agricultural systems.

27 **Keywords:** Municipal sewage sludge; cereal straw; thermal gasification; phosphorus fertilizer ash; heavy metals

28 1 Introduction

- 29 Phosphorus (P) is an essential macro nutrient and the availability of P in agricultural systems is often a limiting
- factor especially in older soils as the ones found in mid and lower Africa, Asia and Australia [1–4]. The main
- 31 source for P fertilizer, mined phosphate rock, is a critical non-renewable globally demanded resource and there
- 32 is an increasing concern about the commercial availability of this resource in the near future (Cordell and
- 33 White, 2014). Determinations of the P depletion rate and especially quantifications of the remaining P resource
- have been the subject of a recent scientific debate (Edixhoven et al., 2013; Scholz and Wellmer, 2016, 2013),
- but it is generally agreed on that the geopolitical importance of the P resource is increasing as is the urgency of
- 36 developing more efficient P management strategies (Chowdhury et al., 2016; Ott and Rechberger, 2012).

A substantial proportion of P used in agriculture ends up in municipal sewage sludge (MSS) (Kahiluoto et al.,

- 38 2015), and recycling this fraction via direct application of MSS to agricultural soil has been considered a cheap
- and efficient way to enhance and fertilize soils (Chowdhury et al., 2016; Fytili and Zabaniotou, 2008;
- 40 Linderholm et al., 2012). However, the extent of direct MSS soil application varies greatly among countries and
- 41 regions, and the variation is caused by many different factors including practical alternatives, differences in
- 42 sludge quality as well as political and cultural restrictions (Fytili and Zabaniotou, 2008; Hukari et al., 2016;
- 43 Kelessidis and Stasinakis, 2012). In recent years, there has been a growing concern in many countries of the
- 44 potential risks associated with the content of emerging organic pollutants and xenobiotics in MSS, including
- antibiotics, fragrances, UV-filters, antiseptics, micro plastics, phthalates, hormones and much more (Choban
 and Winkler, 2008; Igos et al., 2012; Krüger et al., 2014; Michael et al., 2013). As a consequence of this growing
- 47 concern, there is an increasingly restrictive political attitude towards direct application of sewage sludge in
- 48 many countries (Krüger and Adam, 2015), and alternative management options are continuously developed
- 49 and implemented. Thermal gasification of sludge is one of these alternatives (Qian and Jiang, 2014).

50 All types of thermal conversion of municipal sewage sludge leads to production of one or more ash- and/or 51 char fractions. The quality and quantity of these products can vary substantially with the quality of the parent 52 sludge and the design of the thermal process (Fericelli, 2011; Jakobsen and Willett, 1986; Li et al., 2015; Qian 53 and Jiang, 2014). Many scientific studies have been conducted to examine the potential application of 54 incineration ashes and pyrolysis chars in agricultural systems as fertilizers and/or soil enhancers. These studies 55 usually involve investigation of one or several of the following characteristics: Content and type of toxins; fate 56 and mobility of heavy metals; determination of eco-toxicity levels; content and availability of macro- and micro 57 nutrients; technical routes for down-stream upgrading and potential long-term carbon sequestration (Fraser 58 and Lum, 1983; Furr et al., 1980, 1979; Hossain et al., 2015; Jakobsen and Willett, 1986; Liu et al., 2014; Lu et 59 al., 2013; Mellbye et al., 1982; Méndez et al., 2012; Song et al., 2014; Sousa and Figueiredo, 2015). However, to 60 this date, no published studies on the fertilizer quality of ashes and chars from thermal gasification of 61 municipal sewage sludge have been identified. Most studies on thermal gasification of sewage sludge are 62 focused on the potential energy recovery, the technical feasibility of the process and the gas quality (Manara 63 and Zabaniotou, 2012; Seggiani et al., 2012; Zhu et al., 2015).

The aim of this study was to test the use of two Low-Temperature Circulating Fluidized Bed Gasifiers (LT-CFBs) to convert MSS focusing on the quality of the solid process residuals and the potential use of these solid products as fertilizers and/or soil enhancers. Gasification ashes were collected from two MSS campaigns, two MSS/straw co-gasification campaigns and a straw reference campaign. Ash analysis included i) Composition and elemental balances of macro nutrients and heavy metals; ii) pH measurements and iii) incubation studies and pot experiments to determine phosphorus fertilizer quality.

This work is part of a larger assessment of the suitability of the LT-CFB gasification technology as a platform to
 convert municipal sewage sludge to electricity, heat and ash fertilizer. The complete assessment is composed
 of the following two parts:

- Part 1: Assessment of process feasibility and stability, process performance and energy efficiency,
 product distribution and gas product characteristics (Thomsen et al., 2016)
- Part 2: Characterization of LT-CFB ashes as P fertilizer and determination of key elemental balances
 (this study)

77 2 Materials and Methods

78 2.1 The LT-CFB gasifier

79 Two LT-CFB units currently exist; a 100 kWth pilot scale plant at the Technical University of Denmark located at

- 80 Risø near Roskilde, Denmark, and a 6 MWth demonstration unit at DONG Energy's Asnaes Powerplant in
- 81 Kalundborg, Denmark. Both plants are involved in the present study. The LT-CFB technology is commercially
- 82 registered as the Pyroneer Gasifier by DONG Energy and has been described previously (Ahrenfeldt et al., 2013;
- 83 Narayan et al., 2016; Nguyen et al., 2013; Nielsen, 2007; Thomsen et al., 2016, 2015). A generalized process
- 84 flow chart of the LT-CFB gasifier is provided in Figure 1.

85

Figure 1: Illustration of a Low Temperature Circulating Fluidized bed (LT-CFB) gasification system with indications of the main input
 and product streams. Adapted from (Thomsen et al., 2015)

88 2.2 The sewage sludge fuels and LT-CFB campaigns

- 89 The applied MSS samples originated from three different Danish wastewater treatment plants (WWTPs) and
- 90 the samples were collected at different seasons. The three WWTPs that supplied the sludge samples for the
- 91 study are characterized as follows:
- 92 Stegholt WWTP (Aabenraa, Denmark): Constructed as a Mechanical-Biological (active sludge loop)-Nitrification-
- 93 Denitrification-Chemical cleaning facility (MBNDC). However, the use of precipitation chemicals for P capture

has been phased out through constant process optimization. Iron chloride is still applied in the clarifiers to
optimize the sedimentation of floating sludge. The MSS is treated by thermophilic anaerobic digestion for up to

96 18 days at the WWTP before it is dewatered mechanically and exported.

97 Randers WWTP (Randers, Denmark): A representative Danish MBNDC where P is captured approximately 50%

- biologically and 50% chemically using a mix of iron chloride and aluminum. This estimation is based on the
- annual use of precipitation chemicals at the time of the LT-CFB experiment and an assumption of a 1:1.8
 capturing rate for aluminum and of 1:3 for iron. All sludge goes through the active sludge cycle before it is
- capturing rate for aluminum and of 1:3 for iron. All sludge goes through the active sludge cycle before it is
 digested anaerobically in a mesophilic process with a retention time close to one month. The sample for the LT-
- 102 CFB campaign was dried at the WWTP in a Krüger BioCon dryer with temperatures ranging from 100-175 °C.
- 103 Bjergmarken WWTP (Roskilde, Denmark): Another representative Danish MBNDC facility where precipitation
- 104 chemicals are added before the active sludge cycle and phosphorous is captured approximately 70%

biologically and 30% chemically. Iron chloride sulfate and aluminum chloride is used to capture P and

106 precipitate sludge. All sludge goes through the active sludge cycle before it is digested anaerobically for almost

107 three weeks in a thermophilic digestion process. After digestion, the sludge is mechanically dewatered and

- 108 dried in a Krüger BioCon dryer (100-175 °C). MSS products can be delivered as de-watered sludge, as dry
- 109 granules or as dry pellets.
- 110 The LT-CFB campaigns include a reference campaign on straw (REF campaign), two campaigns on mono sludge
- 111 fuels (SLU campaigns) and two campaigns with co-gasification of sludge and straw (MIX campaigns). A short
- description of the campaigns is provided in Table 1. More details and data on fuels and LT-CFB campaigns can
- be found in part 1 of the study (Thomsen et al., 2016). The fuels applied in the MIX-ST and MIX-BJ experiments
- 114 have been designed to provide ashes with P:K relationships around 1:2.

- 118 Proximate analysis of fuels samples (Thomsen et al., 2016) have shown substantial differences among the
- different fuels with regard to moisture content (5-30 wt% as received) and ash content (8-43 wt% dry basis)
- 120 whereas the content of volatile organics (43-69 wt% dry basis) and recalcitrant carbon (14-24 wt% dry basis) as
- 121 well as the higher heating value (11-16 MJ/kg as received) were more comparable.
- Ash samples have been collected from the secondary cyclones (SC, Figure 1) in all campaigns. In addition to the
- 123 SC ashes, a filter ash sample from the SLU-BJ candle filter as well as a final composition char reactor (CR) bed
- sample from the MIX-ST and SLU-BJ campaigns and a size separated sand-free char reactor bottom ash sample
- 125 from the SLU-BJ campaign were collected. 2-5 kg of each ash sample was collected.

126 2.3 Analytical procedures

127 Ash samples were examined on dry basis for their content of volatile material, recalcitrant carbon and ash 128 using standards ASTM D3174-73, DS/EN 14775 (2009) and EN 15169 (2007).

- Higher Heating values were measured by a calorimetric method using a Parr 6300 Bomb Calorimeter andDS/EN 14918 (2010).
- 131 The inorganic compositions of fuels, chars and ashes from REF, MIX-ST and MIX-BJ campaigns were determined
- by an external laboratory, FORCE Laboratory, using a combination of DS/EN ISO 11885 (2009), DS/EN 15290
- 133 (2011), inductively coupled plasma optical emission spectrometry (ICP-OES) and inductively coupled plasma
- 134 mass spectrometry (ICP-MS). Cl was determined using DS/EN 15289 (2011) while Hg was determined using EPA
- 135 7473 (2007). Samples from the SLU-RA campaign was analyzed at the external laboratory at Kommunekemi A/S
- using standard DS259 for preparation and digestion of the samples and ICP-MS by the DS/EB ISO 17294-1-2
- 137 standard for the subsequent analysis. Samples from SLU-BJ have been analyzed by ICP-OES (Optima 5300 DV,
- 138 Perkin Elmer, USA) using the procedure described by Hansen et al. (2009) (Hansen et al., 2009) after digestion
- 139 with HNO_3 , H_2O_2 and HF.
- 140 Total C and N content was measured at the Center for Permafrost of the Department of Geosciences and
- 141 Natural Resource Management, University of Copenhagen, by Dumas combustion (1020 °C) on an elemental
- 142 analyser (CE 1110, Thermo Electron, Milan, Italy).
- The pH was determined by mixing 1 g of dry, grinded ash or sludge with 25 ml of milliQ water before shaking (1
 hour), settling of suspended particles and measurement on a pH meter (Mettler-Toledo AG, Switzerland).
- 145 Elemental balances have been conducted based on the product distribution determined in part 1 of the study146 (Thomsen et al., 2016) combined with the fuel and ash compositions.

147 2.4 Determination of plant available P in ash

- 148 Assessment of P fertilizer quality of the ashes was conducted in two experiments: i) a short-term soil
- 149 incubation study screening sludge and ash samples from all campaigns with subsequent assessment of water
- 150 extractable P; ii) a plant pot experiment measuring barley aboveground biomass production and P uptake with

- 151 SC ashes from the MIX-ST campaign as P fertilizer. The soil selected for the study was taken from the upper
- 152 layer of an agricultural field at DTU, Roskilde Campus (55°41'N, 12° 05'E) and contained 10% clay, 12% silt, 46%
- fine sand and 30% coarse sand. The soil was air-dried and sieved to obtain the fraction ≤ 2 mm for the
- incubation study and ≤ 1 cm for the pot experiment. The soil had a total carbon (C) content of 12 g kg⁻¹, a total
- nitrogen (N) content of 1.1 g kg⁻¹, a bicarbonate-extractable phosphorus (Olsen-P) content of 6 mg kg⁻¹, an
- 156 extractable K content of 69 mg kg⁻¹ and a pH of 5.9 (water).

157 2.4.1 Soil incubation study:

- 158 All MSS and ash samples were ground in a Mahlkönig Kenia Disc grinder (MAHLKÖNIG GmbH & Co. KG,
- 159 Hamburg, Germany) and particles larger than 0.125 mm were extracted by sieving on a Retsch Vibro Sieve
- 160 (Retsch GmbH, Haan, Germany) and subsequently crushed in a FRITSCH Mortar Grinder Pulverisette 2 (Fritsch
- 161 GmbH, Idar-Oberstein, Germany). Sieving and crushing of the large particle fraction was repeated until at least
- 162 90% of the total sample mass passed a 0.125 mm sieve and all particles were smaller than 0.25 mm. Final
- 163 particle size distribution of the samples was determined using sieves 25 μm, 75 μm, 125 μm and 250 μm.
- 164 Triplicates of 50 g soil/quartz sand mixture (50:50 w/w) were mixed with ash samples at a rate of 80 mg P kg⁻¹
- soil by thorough shaking and watered with demineralized water to 50% of the soil's water holding capacity.
- 166 Mass fraction of sludge and ashes in the mixtures were: Mono-sludge ashes (SLU) = 0.1%, Dry sludge (SLU &
- MIX) = 0.2%, Mix ashes (MIX) = 0.3% and straw ash (REF) = 2%. Substrate-free controls and mineral P (KH_2PO_4)
- 168 dosed reference samples were included. Samples were incubated in a climate chamber at 85 % RH and 20 °C
- 169 for 1 week. After incubation, 0.75 g sample (dry basis) was shaken with 45 ml of purified water for 1 hour in a
- 170 50-ml Falcon tube, centrifuged (1 min, 3500 rpm), and the supernatant was filtered through a Whatman no. 5
- 171 filter paper. Extracts were stored at 4°C before analysis of water extractable P on a Flow Injection Analyzer
- 172 (FIAstart 5000, FOSS, Denmark).

173 2.4.2 Plant pot experiment

For the pot experiment, the MIX-ST ash material was incorporated into a mixture of soil and quartz sand (50:50 174 175 w/w) at a rate of 0, 40, 60, 80, and 100 mg total P/kg dry soil with 4 replicates per treatment. Pots (2.5 kg soil substrate) receiving mineral P-fertilizer (KH₂PO₄) or straw gasification ash from the REF campaign at the same 176 177 total P rates were set up as positive controls. A negative control not receiving any P fertilizer was also included. K₂SO₄ was added to all treatments except the REF treatment and the MIX-ST treatment at the highest P rate to 178 give a final concentration of 200 mg K kg⁻¹ dry soil. CaCl₂x2H₂O (20 mg Ca kg⁻¹ soil), MgSO₄x7H₂O (9 mg Mg kg⁻¹ 179 soil), NH₄NO₃ (50 mg N kg⁻¹ soil) and micronutrients (3 mg Mn, 1.2 mg Zn, 0.5 mg Cu, and 0.07 mg Mo kg⁻¹ soil, 180 respectively) were further added to each pot. During the course of the experiment, all pots received another 9 181 mg Mg kg⁻¹ soil and 175 mg N kg⁻¹ soil. Pots were randomized and placed in a growth chamber with a 16 h day⁻¹ 182 photoperiod and an average temperature of 24 /16 °C (day/night). Six seeds of spring barley (cv. Iron) were 183 184 sown into each pot, which were thinned to three plants after emergence. Pots were regularly watered to 185 maintain soil moisture at ca. 60% of the soil's water holding capacity. The aboveground biomass of barley 186 plants was harvested after 7 weeks of plant growth, dried in an oven at 70°C for 48 h and weighed. The dry 187 plant material was finely ground and a subsample was wet-digested in a solution of nitric and perchloric acid

(4:1, v/v). Total P concentration in the digest was measured on an AutoAnalyzer 3 (Bran+Luebbe, Norderstedt,
 Germany).

190 Statistical analyses were carried out using STATISTICA software (Statsoft Inc. 2010). All tests of significance

191 were conducted at $P \le 0.05$. When data were not normally distributed or showed heterogeneity of variances,

192 they were log-transformed before analysis. Data was analyzed with a one-way ANOVA and when significant F-

193 tests were obtained, multiple mean comparisons were carried out using Tukey's Honest Significant Difference

- 194 (HSD) test.
- 195

196 3 Results and discussion

197 **3.1** Proximate analysis of ash samples

198 Results from the proximate analysis of the ash samples showed much lower ash content in the MIX and REF SC199 ashes than in the SLU ashes (Table 2).

Campaign	Ash sample	Volatiles % DM	Recalcitrant carbon % DM	Ash % DM
SLU-BJ	SC ash	1.4±0.3	3.0±0.2	95.7±0.2
SLU-RA	SC ash	1.1±0.3	4.3±0.9	94.6±0.9
MIX-ST	SC ash	8.9±0.1	27.6±1.3	63.5±1.3
MIX-BJ	SC ash	5.0±0.2	22.0*	73.0*
REF	SC ash	6.3±0.3	36.7*	57.0*
SLU-BJ	Filter ash	1.6±0.2	3.5±0.1	94.9±0.1
SLU-BJ	CR bottom ash	1.8±0.1	2.6±0.2	95.6±0.2

200 Table 2: Proximate analysis of dry ash samples. DM: Dry matter. SC: Secondary cyclone. CR: Char reactor.

201

202 Likewise, the content of volatile organic material was a factor of 4-8 higher in the MIX and REF SC ashes than in 203 the SLU ashes while the content of recalcitrant carbon was a factor of 5-12 higher. Despite the differences in 204 the total quantity, the ratio between the volatile and recalcitrant carbon was found to be relatively stable (0.2-205 0.5) among all SC ashes. Applying data on the proximate composition of the fuels as well as product 206 distribution from part 1 (Thomsen et al., 2016) it is estimated that the degree of conversion of volatile organics 207 was around 99% in all campaigns, and that the degree of conversion of recalcitrant carbon varied between 82-208 86% in the MIX and REF campaigns and 94-95% in the SLU campaigns. The data cannot be used to suggest, 209 which materials will provide the most recalcitrant carbon for soil sequestration, but there will be a much larger 210 potential pool of recalcitrant carbon as well as volatile organics in the ashes from co-gasification than in the 211 ashes from MSS gasification alone.

213 **3.2** Elemental analysis and elemental mass balance

214 Most of the N originally present in the fuel was transferred to the gas phase while the C content in the ashes

215 varied substantially with the type of fuel (Table 3).

Campaign	Sample	Total C % DM	Total N % DM
SLU-BJ	Sludge	27.6±0.1	3.9±0.0
SLU-RA	Sludge	28.7±0.4	3.9±0.1
MIX-ST	Sludge	30.6±0.1	4.4±0.0
MIX-BJ	Sludge	27.6±0.1	3.8±0.0
SLU-BJ	SC ash	4.2±0.0	0.4±0.0
SLU-RA	SC ash	6.7±0.1	0.4±0.0
MIX-ST	SC ash	25.5±0.0	0.7±0.0
MIX-BJ	SC ash	23.8±0.2	0.4±0.0
REF	SC ash	44.5±0.3	0.4±0.0
SLU-BJ	Filter ash	5.2±0.0	0.4±0.0
SLU-BJ	CR ash	7.1±0.1	0.4±0.0

Table 3: C and N content of fuels and ashes. DM: Dry matter. SC: Secondary cyclone. CR: Char reactor.

217

218 Combining data from Table 3 and the ash production rates from the different campaigns (Thomsen et al.,

219 2016), it is determined that in mono-sludge campaigns 1-2 % of the fuel N is recovered in the SC ash and 0-1%

is captured in the Filter ash. In the reference campaign and the two mix campaigns, 4-5% of the fuel N is

recovered in the SC ashes. From an N-conservation point of view, it seems like there is an advantage from cogasification in this regard, especially since the N concentration in dry sludge fuels can be expected to be at least
4-5 times as high as in dry mix and straw fuels (ECN, 2016a, 2016b). However, plant availability of N in sewage
sludge biochar is reported to be substantially lower than in the feedstock, decreasing with increasing

225 conversion temperature (Wang et al., 2012).

226 LT-CFB ashes produced from straw have previously been found to be highly suitable for carbon sequestration 227 and provide other soil benefits as well (Hansen et al., 2015). However, the very low carbon content in the 228 mono-sludge SC ashes decreases the potential effect of using these ashes to sequester carbon and increase the 229 content of organic carbon in soils, and could also affect other common biochar characteristics like high cation 230 exchange capacity, water retention etc. In this regard co-gasification of MSS and straw is also found to have an 231 advantage compared to mono-gasification of MSS. Char from MSS pyrolysis as well as ashes from straw 232 gasification has recently been shown to increase these soil fertility parameters significantly, but no studies on 233 the effect of ashes from MSS gasification or co-gasification have been found (Hansen et al., 2016; Sousa and 234 Figueiredo, 2015).

235 When ash is considered as a fertilizer, the content of major nutrients P and K is especially interesting.

The P content in sludge is substantial while the K content is quite low. In straw, the relationship is the opposite. In mixed fuels it is thereby possible to design a P-K relationship suitable for agricultural use (Figure 2).

□ Al ■ Ca ■ Fe ■ K ■ Mg ■ P ■ S

238

Figure 2: Content of selected elements in fuel and ash samples. Results given in % of dry mass (%DM). SC: Secondary cyclone. CR: Char reactor.

If including the content of recalcitrant carbon as a key characteristic of the ashes, the relationship between
carbon, phosphorous and potassium can be expressed roughly as C:P:K = 1:1:0 (SLU-BJ & SLU-RA), 10:1:2 (MIXST), 10:1:4 (MIX-BJ) and 110:1:21 (REF). The optimal P:K ratio will vary with soil, plant and climate, but the
obtained results clearly indicate that it is possible to design the SC ash fertilizer in a very wide range of
compositions depending on the MSS:straw ratio in the fuel. This is very important in regard to optimal
utilization of P and K resources and economical value of the fertilizer ashes.

The content of aluminum (Al) and especially iron (Fe) has been found to have a profound negative influence on
the plant P availability in sludge and deriving ashes (Krogstad et al., 2005; Pettersson et al., 2008). The ratio
between Al and Fe in sludge was largely maintained in the ashes, and concentrations were increased with 100650% and 50-550% respectively.

- 251 Other elements such as magnesium (Mg), calcium (Ca) and sulfur (S) are also valuable plant nutrients contained
- in ashes (Nieminen et al., 2005). The content of Ca (1-13%) was found to be very high in ashes from mono-
- sludge campaigns. The concentrations of Ca and Mg in the ashes increased with 50-550% and 50-650%
- respectively while the concentrations of S in the ashes were 15-170% of those in the corresponding fuel.

However, plant availability of these elements in the ash products might vary, as shown in experiments byNieminen et al (2005) using wood ash (Nieminen et al., 2005).

257 When applying sludge or ash as fertilizer or soil enhancer, the content of heavy metals is usually strongly

regulated. In Denmark, heavy metals in sludge and ash are regulated either per unit of dry mass or per unit of

total P mass. In the European Union, the regulation is per dry mass. Both set of results are included in Table 4.

Table 4: Contents of selected heavy metals in fuels and ashes. Results as mg heavy metal per kg dry matter (DM) and per kg total P.

263 *(Danish Ministry of the Environment, 2008)

264 Legal thresholds per basis of dry mass were breached several times for contents of cadmium and nickel and a few times for lead and mercury. The thermal process concentrated thermally stable elements in the ashes as 265 266 also observed in the assessment of major fertilizer elements (Figure 2), which is a severe drawback in regard to 267 legal thresholds on basis of mass. With the regulation of heavy metals per unit of P, the pattern is different. For 268 nickel and lead, the thermal gasification increased the concentration per unit of P, but the level of increase 269 varied, and in a few cases the concentrations were even decreased. Ni content per unit of P increased 270 substantially in all 100 kW campaigns (SLU-BJ, SLU-RA and MIX-ST). Little or no P is expected to be lost at the 271 low temperatures, and the increase in the Ni/P is expected to be due to leaching of Ni from the CR reactor steel 272 lining as also observed in a study by Hernandez et al. (2011) (Hernandez et al., 2011). The pattern was not 273 expressed in the 6 MW campaign (MIX-BJ), and this is consistent with the hypothesis, as the 6 MW CR reactor 274 has inner refractory lining.

For cadmium and mercury there was a profound reduction per unit of P in all cyclone and bottom ash fractions collected. Mercury was almost completely removed in all ashes while the content of cadmium per unit of P was

reduced with 13-96%. These findings are very important as mercury and cadmium are often considered the

278 most problematic heavy metals when using MSS or ashes in agriculture (Roberts, 2014; Werther and Ogada, 279 1999). The cadmium content per unit of P decreased significantly in SC ashes but much more in CR ashes. 280 Furthermore, the reduction of Cd per unit P in SC ashes as well as in CR ashes compared to their parent fuels 281 was a lot higher in MIX campaigns than in mono-sludge campaigns. During the thermal process, cadmium is 282 evaporated out of the particulate matter and into the hot gas phase as a result of the temperatures in the 283 pyrolysis and char reactors. Elemental cadmium melts at 321 °C and has a fairly high vapor pressure around 50 284 kpa at 720 °C. Another relevant Cd-species is cadmium chloride (CdCl₂), which melts around 568 °C but has a 285 vapor pressure generally a factor of 10 lower than elemental cadmium (Skudlarski et al., 1987; Stull, 1972). 286 Some of the Cd liberated to the gas phase in the hot CR is probably re-condensed on the surface of particulate 287 matter in the colder secondary cyclone. This explains the elevated Cd-concentration in the SC ash compared to 288 the CR ash. Through the secondary cyclone, the gas temperature drops to around 600 °C. At this temperature 289 the vapor pressure of cadmium has decreased with almost a factor of 5 compared to the char reactor 290 environment. As the gas cools further towards the filter, even more Cd is condensing out on entrained and 291 captured particles. This explains the high Cd/P relationship in the SLU-BJ filter ashes, which was more than 292 three times higher than in the fuel, 4 times higher than in the SC ash and 13 times higher than in the CR bottom 293 ashes. Based on the high toxicity of Cd, it is essential to keep the particle temperatures as high as possible in 294 the separation processes following the gasification. If ash separation and handling is properly addressed, the 295 LT-CFB sludge treatment can in this way be used to recover P for use in agricultural systems where it would 296 otherwise be banned. The hot gas candle filter applied in the SLU-BJ campaign was found to collect more than 297 half of the released cadmium, and this could be an important aspect in relation to downstream treatment of 298 product gas or boiler exhaust gas. Lowering the temperatures in the filter would most likely increase the Cd 299 recovery in this part of the system.

Elemental system balances of the SLU-BJ and MIX-ST campaigns have been established for selected nutrients
 and heavy metals (Figure 3 and Figure 4).

303 Figure 3: Elemental balance of SLU-BJ. Results given as element recovered in percent of element in fuel + virgin bed material

304

305 Figure 4: Elemental balance of MIX-ST. All results given as element recovered in percent of element in fuel + virgin bed material

306 The uncertainty related to the elemental mass balance is significant but a few strong trends can be derived. 307 The substances Mg, P, Ca, K and Cr were allocated quite consistently to the SC ash of both campaigns, but the 308 distribution among the CR accumulation and gas phase was less consistent. In the SLU-BJ campaign the main 309 inconsistency seems to relate to the Ni balance. The Ni-balance gap supports the theory previously presented 310 regarding steel alloy leaching in the 100 kW campaigns. However, this is not supported by the MIX-ST results 311 indicating that there is a big influence of the fuel and ash composition on the release of heavy metals. It is 312 expected that the increase in total system CI content by co-gasification with straw can facilitate additional 313 release of heavy metals as also seen in Cd and Cr balances. This approach has been studied extensively as a 314 MSS ash upgrading method (Adam et al., 2009; B Nowak et al., 2012; Benedikt Nowak et al., 2012; Vogel et al., 2011). The remaining results of the SLU-BJ campaign are in quite good agreement with the results from a series 315 316 of tests conducted in a Circulating Fluidized Bed gasifier in Finland in the late 1990's (Kurkela, 2010).

317 3.3 pH

318 The pH values of the sludge samples were close to 7 for all materials (Table 5). Gasification consistently

319 increased pH compared to the respective sludge fuels to values between 10 and 11.

Table 5: pH of sludge and ash samples in water. Maximum deviations between duplicates < 0.5%. SC: Secondary cyclone. CR: Char
 reactor.

323 3.4 Ash P fertilizer quality assessment

324 3.4.1 Soil incubation study

In the incubation study conducted, fuel mixes and straw fuels were not applied as they do not have practical relevance as pure P fertilizers due to very low P contents (Figure 2). The P concentration in the REF SC ash is

327 also too low for use as pure P fertilizer, but it is included for interpretation of the mixed fuel ashes.

328

Figure 5: Water extractable P in soil after the amendment with sludge and ash samples, relative to the mineral P reference. Values of the non-amended control soil have been subtracted. SC: Secondary cyclone. CR: Char reactor.

331 The screening results in Figure 5 show reduced plant P availability in all incubated SC ashes compared to their 332 parent sludge samples. The results also show that MIX ashes perform slightly better than all SLU ashes. In a previous study, co-pyrolysis of slaughterhouse waste with wood and corn residues have been found to lead to 333 334 a beneficial modification in the P species and an increase in the P solubility and P fertilizer quality (Zwetsloot et al., 2015). It is therefore hypothesized that a similar effect could be part of the explanation behind the 335 336 improved P availability of MIX ashes in the incubation study. However, with the current set of results, the 337 influence from variations in the sludge composition cannot be distinguished from the influence of the co-338 gasification with straw to an extent where it is actually possible to conclude if there is a significant 339 improvement in the P quality. The mono-straw SC ash (REF) has a comparatively high plant available P pool, 340 which makes it difficult to conclude on the optic of the potential improvements in the MSS P from go-341 gasification. The good REF P result could be due to the P speciation alone but might as well be due to influence of other ash characteristics. As the P content of the REF SC ashes is very low, the dosage of REF SC ashes was a 342 343 lot higher than for the other ashes – by weight as well as volume. Therefore, the potential effects on other soil 344 parameters such as pH are expected to be higher for this ash than for the others.

345 The MSS sample and SC ash from Randers WWTP (SLU-RA) performed worse than the comparable MSS and SC ash samples. This may be expected from the fact that the dosing of Al and especially Fe-based precipitation 346 347 chemicals, which have the ability to form highly insoluble aluminum- and iron phosphates, is higher at Randers 348 compared to the other WWTPs (Parés Viader et al., 2015). However, despite the fact that the use of metal 349 based precipitation chemicals is higher at Bjergmarken WWTP than at Stegholt WWTP, no obvious difference 350 between MSS or ash samples from the two MIX-campaigns are obvious. Measured per unit of total P, the Al content in the sludge from Bjergmarken is almost a factor of 1.5 higher than the Al content in sludge from 351 352 Stegholt. The iron content on the other hand was almost identical in the two sludge samples and exactly the 353 same in the mixed samples. Assuming that the metal-based precipitation chemicals in general have a strong 354 influence on the P-solubility, these results could indicate that the iron content is a more important influence on 355 the P water solubility than the aluminum content. This is corroborated by a study of Pettersson et al. (2008), 356 who reported P extraction from sewage sludge ashes being more difficult when P had been precipitated with 357 Fe than with Al-based chemicals (Pettersson et al., 2008).

The SLU-BJ filter ash performed better than the SC ash and CR bottom ash from the same campaign in terms of P availability. From the data in Figure 2 the main differences in the elemental composition between the ash fractions seem to be an increased content of alkali metals (Ca and K) per unit of P in the filter ash. This is also a general trend in the MIX and REF ashes showing higher P availability compared to the SLU ashes. However, despite the higher amount of available soil P after application of the filter ash compared to the SC ash and CR ashes, the high relative content of heavy metals Ni, Cr and especially Cd makes this ash unsuitable for agricultural application.

365 3.4.2 Plant pot experiment

366 Without added P, the growth of the barley plants was extremely restricted (only 2.9 g DM per pot,

368 Figure 6) and the addition of mineral P as well as ash greatly improved plant dry matter production already at

- 40 mg P kg⁻¹ soil. As observed in previous experiments (Müller-Stöver et al., 2012), REF straw ash was very
- 370 effective in supplying P to the plants, especially at higher application rates. Only at the lowest dosage applied,
- 371 REF ash application resulted in a significantly lower dry matter yield compared to mineral fertilizer, while at all

372 other dosages, the same amount of plant dry matter as with mineral fertilizer could be produced with ash.

373 However, plant P uptake (

Figure 6) still showed the differences between P availability in the two materials, indicating that P uptake from

375 mineral P at the higher dosages was already beyond a level that still increases biomass production. In contrast,

the application of the MIX-ST ash - although also showing a strong positive dose-yield response and an

377 increasing relative effectiveness compared to mineral fertilizer- did never result in the same dry matter

378 production as the mineral fertilizer. However, P uptake was statistically similar at 60 and 80 mg P kg⁻¹ soil

379 between REF straw ash and MIX-ST ash, and no statistically significant difference in dry matter production

380 could be observed between the two ash treatments at the two highest phosphorus levels (

381

382 Figure 6 and Figure 7). P originating from both fuel components appeared plant-available in the MIX-ST ash,

383 since taking the fuel mixing ratio and the P content of the straw ash into consideration, at the highest

384 application rate a maximum of 10 mg P kg⁻¹ soil could originate from the straw component in the mixed ash.

Figure 6: Shoot dry matter in the treatments receiving mineral fertilizer or two different ash materials in various P application rates. Different letters indicate statistically significant differences within the same application rate. Results on basis of total dry matter.

Figure 7: Plant phosphorus uptake in the treatments receiving mineral fertilizer or two different ash materials in various application
 rates. Different letters indicate statistically significant differences within the same application rate.

Qualitatively, the results of the pot experiment correspond quite well to those of the P screening. However, the performance of the REF and MIX-ST ashes relative to the mineral fertilizer was generally better in the pot experiment than in the simple screening. A weak correlation between water-extractable P and plant P uptake from more complex P sources has been reported previously for rock phosphate (Bationo et al., 1991). Mackay et al. (1984) concluded that although water extraction might be useful to assess relative differences between fertilizer materials such as rock phosphates, it may be misleading when only relying on extraction methods to evaluate their agronomic effectiveness compared to more soluble P sources (Mackay et al., 1984).

398 Conclusion

388

Ash product fertilizer quality has been compared across five successful experimental LT-CFB campaigns with different fuels and plant scales. Four of the fuels were municipal sewage sludge or a mix of sludge and cereal straw. The fifth fuel was a reference straw fuel. Results have indicated that it is possible to modify desired characteristics of char and ash products from sludge gasification by co-gasification with straw in different ratios. If the sludge is dry, the mixing ratio can be from 0-100% sludge.

The P fertilizer quality of ash and char samples was examined as water-extractable P after soil amendment and in a plant pot experiment. Qualitatively, the results obtained after 1-week soil incubation corresponded to the 406 results from the pot experiment. However, fertilizer efficiency of the ash samples had a tendency to be

- 407 underestimated in the short-term assessment, revealing the need for more comprehensive soil-plant
- 408 experimentation also including different soil types and plant species. Nevertheless, ashes from co-gasification
- of straw and sludge had higher plant P availability than ashes from mono-sludge gasification, showing the
- 410 potential to be developed into alternative P-fertilizer products.

411 Co-gasifying straw with sludge consistently increased ash fertilizer quality in regard to NPK composition, P plant

412 availability and by a reduced content of heavy metals especially cadmium. In addition, co-gasification led to a

413 higher content of recalcitrant carbon in the ashes increasing potential for beneficial biochar characteristics and

414 long term carbon sequestration. Extracting ashes from the char reactor was found to yield ashes with an even

lower content of heavy metals than the SC ashes, but the P fertilizer value was at the same time reduced. It

416 was found that LT-CFB gasification of sludge was an effective way to purify and sanitize sewage sludge for

417 subsequent use in agricultural systems, especially when co-gasifying sludge with cereal straw.

418 Acknowledgements

419 The authors deeply appreciate the technical and operational assistance obtained during the LT-CFB

420 experiments and subsequent analytical work and would like to express a special appreciation to Zsuzsa Sárossy

421 and Hanne Wojtaszewski from DTU KT, Lene Vigh and Lena Byrgesen from KU PLEN, Per L. Ambus from KU IGN

422 and DONG Energy A/S. Finally the authors would like to thank the Danish Energy Authority for funding the work
