Significance and impact of the study:

*Vibrio cholerae* has frequently experienced genetic changes with rapid evolution of pandemic clones in the Ganges Delta region. Whole Genome Sequencing can reveal genetic information of current pathogenic *V. cholerae* in Bangladesh which includes CTX genotypes, virulence factors, altered antimicrobial resistance pattern as well as mobile genetic element compared to global pandemic strains. This study data could be used in planning future surveillance strategies in Ganges Delta region by informing new epidemiology of current outbreak strains.

Abstract:

Whole Genome Sequencing (WGS) was utilized to investigate the genomic profile of *Vibrio cholerae* O1 strains, isolated from symptomatic patients in a low-income urban area of Dhaka, Bangladesh. Comparative genomics using bioinformatics tools were applied to identify major virulence factors, biotype and antimicrobial resistance genes in three *V. cholerae* O1 strains (VC-1, 2 and 3) isolated from two case patients. A phylogenetic SNP (Single Nucleotide Polymorphism) based analysis was conducted to infer the relatedness to *V. cholerae* O1 strains isolated elsewhere. The *V. cholerae* strains were the El Tor variant carrying *ctxB1* (standard classical genotype). SNP based global phylogeny revealed that the
three isolates were strictly clonal and the closest neighboring genomes were epidemic clones of *V. cholerae* O1 isolated in 2010 from cholera patients in Pakistan. All strains harbored the integrase gene of the SXT element (*int*$_{SXT}$), antimicrobial resistance genes for aminoglycosides, phenicol, sulphonamide, and trimethoprim except VC-1 that lacked sulphonamide resistance genes. The Multilocus Sequence Typing (MLST) revealed that the strains belonged to sequence type, ST69. The study provides knowledge on current genetic traits of clinical *V. cholerae* O1 circulating in urban household clusters of Bangladesh which may help in predicting emergence of new pandemic strains in Bangladesh.

### Introduction

Cholera has claimed millions of lives globally since the spread of the first pandemic from the Indian subcontinent. Despite ground breaking cholera interventions and diagnostic advancement, cholera cause both endemic and epidemic diseases in Bangladesh (Harris *et al.* 2008). In urban slum areas of Dhaka, four per 1000 people become affected with cholera annually and the number is increasing due to rapid urbanization (Chowdhury *et al.* 2011). Clinical cholera cases in Bangladesh are entirely attributed to the O1 serogroup of *V. cholerae* with occasional sporadic outbreaks caused by the O139 serogroup (Chowdhury *et al.* 2015b). Although, the Classical biotype of *V. cholerae* O1 (*ctxB1* genotype) was extinct from this region since 1992 (Faruque *et al.* 1993; Chowdhury *et al.* 2015a); new variants of El Tor biotype strains producing classical toxin, *ctxB1* (altered strains) emerged in Bangladesh in late 1990s (Nguyen *et al.* 2009). The ‘altered’ biotype strains have replaced the *ctxB3* genotype of the 7th pandemic El Tor strains since 2001 and continued to be the cause of
severe dehydration and morbidity in hospitalized patients (Nair et al. 2006; Chowdhury et al. 2015a; Rashid et al. 2016).

In this study, whole genome sequencing (WGS) combined with the use of bioinformatics tools were used to determine the genomic and evolutionary characteristics of three V. cholerae O1 strains collected from two patients in Dhaka city, Bangladesh. Furthermore, comparative genomic analysis was conducted with spatial and temporal clinical V. cholerae O1 strains available from the public domain to determine the genetic relatedness.

**Results and Discussion:**

The distance between case 1, a girl of 4 years and case 2, a girl of 22 years was 588 m and the households used different water sources.

Two V. cholerae strains were isolated from case 1, i.e. VC-1 and VC-3. The patient was reported to have consumed untreated tap water from a closed roof tank supplied with groundwater. In addition, one V. cholerae strain was isolated from case 2, i.e. VC-2. The patient had consumed untreated communal tap water at home provided from the Dhaka city corporation (WASA). Subsequently, a number of relevant environmental samples such as drinking water, food and environmental swabs from the respective patients’ households were investigated for the presence of V. cholerae but were found negative in culturing.

The three V. cholerae strains belonged to the 7th pandemic serogroup O1(rfbV-O1), serotype Inaba, biotype El Tor variant, ST69, and carried the standard classical ctxB (ctxB1) and El Tor tcpA genotype (ctxB∗rstR∗tcpA∗) (Son et al. 2011; Siriphap et al. 2017). All three strains harbored 10 major virulence associated genes normally seen in clinical serogroup O1.
strains (ctxA, ctxB, zot, ace, tcpA, hlyA, mshA, rtxA, ompU, and toxR) (Finkelstein and Mukerjee 1963; Hasan et al. 2013; Singh et al. 2002) except for the ace gene which was not detected in VC-3. The genes for type III secretion system, cholix toxin (chxA) and heat-stable enterotoxin (stn) were absent in the strains. The three V. cholerae strains harbored similar genetic backbone of 7th pandemic El Tor variant trait which has been the highly dominant type in Bangladesh in recent years (Chowdhury et al. 2015a). Since the emergence of the ctxB1 genotype in early 1990s, a similar temporal change occurred in Bangladesh after 2008 when classical genotype ctxB1 shifted to the Haitian genotype ctxB7 and ctxB1 returned again in 2013-14 (Rashid et al. 2016).

The strains showed a unique deletion in the Vibrio pathogenicity island-1 (VPI-1) gene cluster containing three consecutive gene deletions (VC-0819–0821). Variant of Vibrio 7th pandemic island-2 (VSP-2) was found in all the three genome sequences compared to the prototype N16961 with a deletion of 4 ORFs (VC-0495–0498). Similar variants were isolated in India before 2010 (El Ghany et al. 2014; Imamura et al. 2017). After 2010, another variant with a larger deletion spanning from ORF VC0495 to VC0512 (CIRS101 type VSP-2) became predominant in Kolkata, India and eventually replaced other types (Imamura et al. 2017).

The evolution through the larger deletions may occur due to significant genetic rearrangement within the two loci, at the 3’ end of the VC0498 and VC0511 of the genomic backbone of the island and also the event may be more human host specific (Taviani et al. 2010). In Bangladesh, the most recent report from 2004-2007 on VSP-2 variant of El Tor strains showed a higher prevalence of the CIRS101 variant (Taviani et al. 2010). Our results indicate recent occurrence of genetic shift in VSP-2 which is more similar to prototype 7th pandemic El Tor N16961. Previously, the frequent rearrangements of the variants of VSP-2

This article is protected by copyright. All rights reserved.
islands were also occurring in India and Bangladesh but the explanations for such rearrangements are still unclear (Imamura et al. 2017; Taviani et al. 2010).

All three strains were phenotypic susceptible to CHL, TET, AZM, NEO, GEN, CTX and resistant to CIP, STP, NAL, TMP, SMX and AMP (VC-3 intermediate). Multiple AMR genes were determined of which VC-2 and VC-3 showed identical profile harboring AMR genes for aminoglycosides (strA/strB); sulphonamides (sul2); chloramphenicol (catB9); and trimethoprim (dfrA1). The strains did not show phenotypic resistance to chloramphenicol which is in agreement with a recent report showing that the catB9 gene cassette was associated with very low-level of AMR to chloramphenicol (Kumar et al. 2017). VC-1 contained the same resistance genes as VC-2 and VC-3 except for the sul2 and strA genes. The occurrence of one genetic event may result the deletion as sul2 and strA genes locate right next to each other in the SXT element. Comparison of the specific genomic region in SXT element of VC-1, 2 and 3 with V. cholerae 2010EL-1786 further confirmed the absence of the sul2 gene in VC-1 (Figure 1). The locus deletion was found within 102.017 to 102.832 bp in VC-1 as compared to V. cholerae 2010 EL-1786 genome. Although, absence of sul2 gene in the VC-1 SXT element is unusual, such as sul2 gene deletion in SXT variant types has been reported (El Ghany et al. 2014; Siriphap et al. 2017). In 2009, only one in 38 V. cholerae strains had the deletions of the sul2 gene in a study of hospitalized patients in Chandigarh, India (El Ghany et al. 2014).

All the strains contained the SXT element (intSXT gene) and lacked the integrase genes of class 1 integron (intI gene). Our results corroborate previous findings in Asia and Africa (Iwanaga et al. 2004; Sambe-Ba et al. 2017; Siriphap et al. 2017). The NAL and CIP resistant strains conferred amino acid substitutions in gyrA (Ser83Ile) and parC (Ser85Leu) but did
not harbor the fluoroquinolone resistance \textit{qnrVC1} gene. The genomic organization of the integrating conjugative element (ICE) of the \textit{V. cholerae} strains showed an allelic profile similar to the reference ICE\textit{VchHai} except the 21 common deletions including \textit{floR} in loci VC1786ICE6-9, VC1786ICE14, VC1786ICE21-29, VC1786ICE49-53, VC1786ICE83, VC1786ICE85 (Supplementary Table S5). VC-3 contains VC1786ICE10 loci, a putative transposase, but it was absent in the other two strains. The strains conferring resistance to trimethoprim harbored the \textit{dfrA1} gene and lacked \textit{dfrA18} which reveals the similarity of our strains with ICE\textit{VchInd} (Spagnoletti \textit{et al.} 2014). The Bangladesh SXT elements have highly structural similarity except for a few additional allelic deletions with the clade 1 isolates from Chandigarh, India isolated in 2009 which clustered with earlier outbreak strains of \textit{V. cholerae} from India, Bangladesh and Nepal (El Ghany \textit{et al.} 2014). Similarity with the Indian O1 strains indicates recent acquisition of the SXT element within strains from the same geographical areas.

The SNP analysis revealed the three \textit{V. cholerae} strains being strictly clonal with zero SNP between them in comparison to the identified 390 SNPs identified among the 38 Bangladeshi strains. SNP accumulation depends on temporal signature and approximately 3.3 SNPs per year can be accumulated in the \textit{V. cholerae} core genome (Mutreja \textit{et al.} 2011). The three strains were isolated only 11 days apart and from local cholera outbreaks with two households located in the same community, which likely explains the lack of SNP differences. In Haiti, \textit{V. cholerae} O1 strains from the outbreak in 2010 showed no polymorphic sites where as strains from Haitian patients in 2012 had 195 SNPs (Azarian \textit{et al.} 2014). Moreover, the identical \textit{V. cholerae} O1 clones found in the two case-households and the separate water sources used by the households indicate a contamination source other than water supported by earlier reports of cholera cases in Arichpur neighborhood (Bi \textit{et al.}}
We have found differences in virulence and AMR gene profiles between VC-1 and VC-3 from the same patient; although there was no SNP difference. Moreover, super-integrons of the three strains did not show any diversity. Genetic diversity of *V. cholerae* strains from same patient may occur due to co-infection with multiple environmental strains (Rashed *et al.* 2014). As the three strains were clonal, there would be a possibility of circulation of similar outbreak strains in a short time span and between inter and intra person to person transmission.

The local phylogenetic tree showed that the isolates clustered into two major groups based on temporal patterns: one cluster included strains isolated during the period 1969-2000 and the 2nd cluster included strains isolated during the period 2001-2010 (Figure 2). The three *V. cholerae* O1 strains of this study branched from the group of 2001-2010 strains with their closest ancestral strain being PSC-022 isolated in 2010 which differed with 18 SNPs.

The SNP-based global phylogenetic tree revealed that the 469 *V. cholerae* O1 strains were discriminated by 4,141 high quality SNPs. Our Bangladeshi strains formed a monophyletic branch within a clade consisting of epidemic clones of *V. cholerae* O1 El Tor, isolated from Karachi, Pakistan during a major cholera epidemic in 2010 (Figure 3). The Pakistani clones included in the clade named PSC-1, were of coastal origin and formed a unique clade in the wave three of 7th pandemic lineages (Shah *et al.* 2014). We found 11 SNP differences between strain VC-2 and the closest neighboring genome (S9KCH9) (Supplementary Table S4) which suggests that the strains are closely related. The second nearest genomes of VC-2 with 12 SNPs difference were strains S7KCH20 and PCS-022 isolated from patients in Pakistan and Bangladesh, respectively. Interestingly, S9KCH9 and PCS-022 genomes differ
with only three SNPs suggesting a clonal origin of the *V. cholerae* O1 strains associated with cholera outbreaks in 2010 in Bangladesh and Pakistan.

In conclusion, the current Bangladeshi strains showed a clonal origin from Southeast Asian epidemic progenitor and possess the genetic backbone of current ongoing epidemic *V. cholerae* O1 in Bangladesh with considerably diversity in the pathogenicity islands and SXT elements. Our phylogeny results suggest that current *V. cholerae* O1 strains evolved from recent outbreak strains. Considering the global distribution, our study supports the hypothesis that Bengal Delta region remains the origin ground of cholera and persistent infection occur by either new epidemic clones or reemergence of previously existing clones in this region.

This study provides new insights on cholera epidemiology in Bangladesh using WGS technology together with advanced and easily accessible bioinformatics tools. WGS is a more effective, robust and precise method than other molecular approaches for continuous monitoring and possible control of the spread of new epidemic *V. cholerae* O1 clones in Bangladesh, the land which still holds the title as the home of cholera.

**Methods and materials**

**Ethics**

The study was approved by the Ethical Review Committee (ERC) of International Centre for Diarrheal Disease Research, Bangladesh (ICDDR, B). An informed consent was obtained from the caretakers of the households, household respondents, and patients for collection of rectal swab, both survived.
Collection of epidemiological data

During 4 months period, 37 rectal swabs were taken by trained field staff in case of watery diarrhea reported by household caretaker and demographic, socioeconomic and clinical data were obtained in a brief interview with patients or respondents (in case of child).

Isolation, identification and antimicrobial susceptibility testing

The rectal swabs were cultured for *V. cholerae*, confirmed by PCR for the *ompW* gene (Nandi et al. 2000) and three out of 37 (8.1%) rectal swabs found positive. In October, 2015 three *V. cholerae* O1 strains were isolated from rectal swabs of two diarrhea cases identified during random visits by field staff and a report via choleraphone (mobile phones distributed to households for diarrhea reporting) (Sengupta et al. 2013). The distance between the two households was measured by a global positioning system. Suspected *V. cholerae* strains were isolated from rectal swabs by using standard biochemical, serological assays and a species-specific PCR (Huq et al. 2006; Nandi et al. 2000). According to the standard guideline described by the Clinical and Laboratory Standards Institute (CLSI), antimicrobial susceptibility testing to streptomycin (STP, 10 µg ml$^{-1}$), ciprofloxacin (CIP, 5 µg ml$^{-1}$), chloramphenicol (CHL, 30 µg ml$^{-1}$), trimethoprim (TMP, 5 µg ml$^{-1}$), sulfamethoxazole (SMX, 25 µg ml$^{-1}$), nalidixic acid (NAL, 30 µg ml$^{-1}$), tetracycline (TET, 30 µg ml$^{-1}$), azithromycin (AZM, 15 µg ml$^{-1}$), ampicillin (AMP, 10 µg ml$^{-1}$), neomycin (NEO, 30 µg ml$^{-1}$), gentamicin (GEN, 10 µg ml$^{-1}$), cefotaxime (CTX, 30 µg ml$^{-1}$) (OXOID, UK) was performed by agar disk diffusion method (CLSI 2016). *Escherichia coli* ATCC 25922 was used for quality control.
Whole Genome Sequencing (WGS)

The DNA was extracted from the three isolates for WGS as earlier described (Siriphap et al. 2017). Raw sequence data were deposited to Nucleotide Archive (http://www.ebi.ac.uk/ena) under study accession no.: PRJEB18714. The raw reads were de novo assembled using SPAdes 3.7.0 (Bankevich et al. 2012). The genomic data are included in the supplementary Table S1.

In silico bioinformatics analysis

The web-server tool MyDbFinder 1.1 (https://cge.cbs.dtu.dk/services/MyDbFinder/) and associated database (supplementary Table S1) was used to analyse the assembled V. cholerae genome sequences to identify the species-specific gene, serogroup-specific genes, the biotypes-specific genes, putative virulence genes, ctxB genotype specific genes, pathogenic islands (PAI), and the specific gene of the 7th pandemic strain with a selected threshold of 98% identity (Siriphap et al. 2017).

The acquired antimicrobial resistance (AMR) genes were detected using ResFinder web server (version 2.1, 80% threshold for %ID/ 60% minimum length) (Zankari et al. 2012).

Blast atlas tool (https://server.gview.ca/) was used to further compare the strains with reference V. cholerae 2010EL-1786, Accession No. NC_016445.1 (contain sul2 gene). The SXT element, the class 1 integron, and the presence of mutations in the DNA gyrase (gyrA gene) and in the DNA topoisomerase IV (parC gene) were determined using MyDbFinder and associated database (Supplementary Table S2) (Kaas et al. 2016).
The genotypic profile of AMR determinates was compared with the genome of the 2010 Haiti V. cholerae O1 integrating conjugative element (ICE), ICEVchHai1(JN648379) and dfrA18 gene of SXTMO10 (AY034138) by using MyDBFinder (threshold, 95% identity). The MLST sequence types (ST) for V. cholerae strains were determined using the MLST tool (version 1.8) (https://cge.cbs.dtu.dk/services/MLST/).

**Phylogenetic analysis**

High quality Single Nucleotide Polymorphisms (SNPs) of the three O1 V. cholerae genomes from Bangladesh were identified using the pipeline CSI Phylogeny 1.4 available from the CGE website (https://cge.cbs.dtu.dk/services/CSIPhylogeny/). Raw read data and assembled genomes from 466 V. cholerae global pandemic and outbreak strains obtained from the European Nucleotide Archive (ENA) and GenBank were also analysed to determine genome wide SNPs and a global phylodynamic tree was constructed to map the Bangladeshi strains in a global context as previously published (Kaas et al. 2016). Moreover, a phylogenetic tree was inferred using SNPs differences in 38 genomes of the 7th pandemic V. cholerae O1 El Tor strains from Bangladesh. Raw reads were mapped to the published completed reference strain N16961 (Acc. No.: NC_002505.1) as earlier described (Delcher et al. 2002; Kaas et al. 2016). The sequence information of 466 global strains and the specific SNP differences are included in the Supplementary Table S3 and Table S4. The phylogenetic trees were created and visualized using online tool iTOL (Version 3) (https://itol.embl.de/).
