Abstract

Recombinant Chinese hamster ovary (CHO) cells are able to provide biopharmaceuticals that are essentially free of human viruses and have N-glycosylation profiles similar, but not identical, to humans. Due to differences in N-glycan moieties, two members of the serpin superfamily, alpha-1-antitrypsin (A1AT) and plasma protease C1 inhibitor (C1INH), are currently derived from human plasma for treating A1AT and C1INH deficiency. Deriving therapeutic proteins from human plasma is generally a cost-intensive process and also harbors a risk of transmitting infectious particles. Recombinantly produced A1AT and C1INH (*rhA1AT*, *rhC1INH*) decorated with humanized N-glycans are therefore of clinical and commercial interest.

Here, we present engineered CHO cell lines producing *rhA1AT* or *rhC1INH* with fully humanized N-glycosylation profiles. This was achieved by combining CRISPR/Cas9-mediated disruption of 10 gene targets with overexpression of human ST6GAL1. We were able to show that the N-linked glyco-structures of *rhA1AT* and *rhC1INH* are homogeneous and similar to the structures obtained from plasma-derived A1AT and C1INH, marketed as Prolastin®-C and Cinryze®, respectively. *rhA1AT* and *rhC1INH* produced in our glyco-engineered cell line showed no detectable differences to their plasma-purified counterparts on SDS-PAGE and had similar enzymatic *in vitro* activity. The work presented here shows the potential of expanding the glyco-engineering toolbox for CHO cells to produce a wider variety of glycoproteins with fully humanized N-glycan profiles. We envision replacing plasma-derived A1AT and C1INH with recombinant versions and thereby decreasing our dependence on human donor blood, a limited and possibly unsafe protein source for patients.

1 Introduction

Chinese hamster ovary (CHO) cells serve an important role in the biotechnology industry as the primary workhorse for the production of recombinant protein therapeutics [1]. Many of these therapeutics are glycoproteins that contain one or more N-glycan and/or O-glycan chains. As N-glycans can potentially affect protein folding, immune regulation, cellular homeostasis and the biological half-life of proteins [2, 3], it is considered a critical quality attribute and much effort has been put forth to improve features of protein N-glycosylation. The production of diverse N-glycan structures is a major contributor to the heterogeneity of protein products derived from CHO cells. The inherent heterogeneity of CHO N-glycan profiles is especially a drawback when one distinct N-glycan structure is desired on the protein product. Two examples of human plasma proteins with distinct, homogeneous N-glycan structures are found within the serpin superfamily, alpha-1-

antitrypsin (A1AT) and C1 esterase inhibitor (C1INH) [4]. Patients with the genetic disorders alpha-1-antitrypsin deficiency (AATD) or hereditary angioedema (HAE-C1INH) have decreased plasma levels of functional A1AT or C1INH, respectively, and are currently treated with prophylactic augmentation therapy of plasma purified A1AT or C1INH[5, 6]. Augmentation therapy is cost intensive [5], and C1INH purified from pooled donor plasma has been associated with hepatitis C virus infections prior to the introduction of virucidal methods[7]. Despite current dedicated virus inactivation steps, cases of Hepatitis G transmission have been reported [8] and non-enveloped viruses can still be transmitted via plasma-derived products [9]. Nevertheless, approved C1INH formulas are concentrates purified from human donors (Berinert®, Cinryze) despite containing undesired protein impurities identified as α 1-antichymotrypsin, ceruloplasmin and Factor C3 [6].

Both native human plasma A1AT (*pA1AT*) and C1INH (*pC1INH*) possess a N-glycan profile with ~60–80% diantennary, disialylated, non-fucosylated (A2G2S2) structures with human-like alpha-2,6-linked sialic acids. *pA1AT* has three N-glycosylation sites [4], where natural A2G2S2 structures are not essential for biological activity but enhance *in vivo* half-life and *in vitro* protein stability [10, 11]. *pC1INH* is thought to be one of the most heavily glycosylated plasma proteins and harbors ten O-linked and six N-linked glycan structures [12]. The six N-linked glycan moieties with A2G2S2 as predominant structure have been shown to increase serum half-life and are reported to increase *in vivo* efficacy [13–15].

The ability to generate high A2G2S2 N-glycan proportions on *rhA1AT/rhC1INH* may be critical for improving product quality. Although efforts have been reported, generating high proportions of A2G2S2 N-glycans has not to our knowledge been published. For instance, CHO cells lack active St6 beta galactoside alpha-2,6-sialyltransferase 1 (ST6GAL1) to cap N-glycans with alpha-2,6-linked sialic acids [16]. *rhA1AT* and *rhC1INH* were produced in various platforms [17–29]. However, these approaches revealed low

productivity or the N-glycosylation was far from the profile of *pA1AT* or *pC1INH* and therefore cleared rapidly from the human blood making intravenous administration impractical.

Commercially available *rhC1INH* from transgenic rabbits shows activity similar to *pC1INH* and has decreased virus transmission risk. However, it differs in N-glycosylation profiles from *pC1INH* and therefore reveals a risk of allergy, a dissatisfactory pharmacokinetic profile and consequently is unlikely to be of use in prophylaxis [30]. Glycosylation-engineering in primary human cells aimed to mimic O-glycan profiles of *pC1INH*. However, complete sialylation of *rhC1INH* N-glycan structures was not achieved [31].

To address this, we aimed to engineer the heterogeneous CHO-S N-glycan profile towards a predominantly non-fucosylated biantennary A2G2 structure by combining the publicly available CHO-K1 genome sequence [32], clustered regularly interspaced short palindromic repeats/CRISPR-associated protein 9 (CRISPR/Cas9) for multiplexing gene editing [33], and reported CHO glycosyltransferases [34]. To this end, we made functional knockouts of the *Glul*-gene and nine glycosylation-gene targets (10x KO, Suppl. Table 1). We hypothesized that *rhA1AT* and *rhC1INH* produced in this genetic background with parallel co-expression of *ST6GAL1* would display an N-glycan profile similar to *pA1AT* and *pC1INH* with predominant A2G2S2 N-glycan structures. We present CHO clones producing *rhA1AT/rhC1INH* similar to *pA1AT/pC1INH* when assessed by N-glycan analysis, protein activity, SDS-PAGE and isoelectric focusing. CHO derived *rhA1AT* and *rhC1INH* with fully humanized N-glycan profiles have the potential to replace the cost-intensive and possibly unsafe plasma-based augmentation therapy of AATD and HAE-C1INH patients without compromising activity and N-glycosylation.

2 Materials and methods

2.1 sgRNA, GFP_2A_Cas9 and A1AT/C1INH_ST6GAL1_Glul plasmid design

GFP_2A_Cas9 and single guide RNA (sgRNA) plasmids were constructed as previously described [33]. The sgRNA target design for Mgat4A, Mgat4B, Mgat5, St3gal3, St3gal4, St3gal6, B3gnt2, Fut8, Sppl3 and Glul was performed using “CRISPy” [35]. The target sites for the mentioned genes and the oligos for sgRNA cloning are listed in Suppl. Table S1 and Table S2, respectively.

Plasmids for co-expression of A1AT/C1INH and ST6GAL1 were constructed with uracil-specific excision reagent cloning method as previously described [36, 37] (Suppl. Fig. 1). The DNA sequences of the plasmids are listed in Suppl. Table S5.

2.2 Cell cultivation and transfection for genome editing

CHO-S suspension cells were incubated in a humidified incubator at 120 rpm, 37°C, 5% CO₂, passaged to 2-3 x 10⁵ cells/mL every 2-3 days and transfected in 6-well plates (BD Biosciences, San Jose, CA) as described previously [33]. The GFP_2A_Cas9 / sgRNA plasmid ratios for each transfection was 1:1 of which the plasmid load of sgRNA was divided equally by the amount of different sgRNAs used per transfection (Suppl. Table S4). To measure FACS sorting efficiency, pmaxGFP® vector (Lonza, Basel, Switzerland) transfection was performed as well. Cells were harvested for fluorescence-activated cell sorting (FACS) 48 h post transfection.

2.3 Single cell cloning of genome edited cells using FACS

Prior to FACS, cells were filtered through a 40 µm cell strainer into a FACS-compatible tube.

Single fluorescent-positive (GFP) cells were sorted into 384-well plates (Corning, New York, NY) containing 30 µL CD CHO medium supplemented with 8 mM L-glutamine, 1.5% HEPES buffer and 1% Antibiotic-Antimycotic (Gibco, Waltham, MA) per well as described previously [38]. For cell sorting, fluorescent-positive cell populations were gated based on non-transfected WT CHO-S cells. Two weeks after cell sorting cell colonies were moved to

96-well flat-bottom plates (BD Biosciences) and expanded for deep sequencing analysis and batch cultivation.

2.4 Deep sequencing analysis

Confluent colonies from 96-well flat-bottom replicate plates were harvested for genomic DNA extraction. DNA extraction was performed using QuickExtract DNA extraction solution (Epicentre, Illumina, Madison, WI) according to the manufacturer's instruction. The library preparation was based on Illumina 16S Metagenomic Sequencing Library Preparation and deep sequencing was carried out on a MiSeq Benchtop Sequencer (Illumina, San Diego, CA). The protocol for amplifying the targeted genomic sequences, amplicon purification, adapter-PCR and following quality analysis was based on previously published work [33]. PCR primers are presented in Suppl. Table S3.

2.5 Transfection and expression in polyclonal cell lines by applying MSX-selection

Cells were seeded in 250 mL Corning vent cap shake flasks (Sigma-Aldrich) as duplicates with cell densities $\sim 1 \times 10^6$ cells/mL in 60 mL CD CHO medium supplemented with 8 mM L-glutamine (Life Technologies) and transfected with 75 μ g of A1AT-Glul-ST6GAL1 plasmid or 75 μ g of C1INH-Glul-ST6GAL1 plasmid (Suppl. Fig. 1) using FreeStyle™ MAX reagent together with OptiPRO SFM medium (Life Technologies) according to the manufacturer's recommendations. 1 μ L/mL anti-clumping agent was added 24 h after transfection. pmaxGFP® vector (Lonza) transfection was performed to measure transfection efficiencies. Two days after transfection, cells were transferred into 60 mL CD CHO medium lacking L-glutamine (Life Technologies) and supplemented with 1 μ L/mL anti-clumping agent and 0 μ M, 10 μ M, 30 μ M or 50 μ M MSX (EMD Millipore, Billerica, MA). Cell densities and viabilities were determined once per day using the NucleoCounter NC-250 Cell Counter (ChemoMetec). The cells were passaged in fresh selection medium every 2-3 days until viability and doubling time reached stable values. Polyclonal cell lines (pools) were seeded in duplicates at $\sim 1 \times 10^6$ cells/mL with corresponding MSX

concentrations. Cell densities and viabilities were determined once per day and supernatants of the pools were harvested three days after seeding and pooled within duplicates for purification of *rhA1AT* and *rhC1INH*.

2.6 Single cell cloning of cells from polyclonal cell pools using FACS

Non-stained single cells were sorted from pools as described above. For cell sorting, all viable cells were gated for sorting into 384-well plates with L-glutamine-free medium. Two weeks after cell sorting the clones were moved to 96-well flat-bottom plates (BD Biosciences) and expanded to shake flask format in CD CHO medium supplemented with 1 μ L/mL anti-clumping agent, 25 μ M MSX and lacking L-glutamine.

2.7 Screening cell pools and single cell clones for human-like α -2,6-sialic acid linkage formation with lectin staining

For lectin staining of cells, triplicates of 10,000 cells per sample were diluted in 200 μ L of 0.22 μ m pore size filtered CD CHO medium (Life Technologies) supplemented with 5 μ g/mL Hoechst 33342 (Merck, Darmstadt, Germany) and 1 μ g/mL Fluorescein isothiocyanate (FITC) labeled *Sambucus nigra* agglutinin (SNA) lectin (Biomol, Hamburg, Germany). After 60 min incubation in the dark at 37°C and 5% CO₂, the cells were washed with 200 μ L CD CHO medium and then washed twice with 200 μ L phosphate buffered saline (PBS) (300g, 5 min, RT). The samples were resuspended in 200 μ L PBS and transferred to 96-well plate for final centrifugation at 300 g for one minute. The percentage of FITC SNA positive cells was determined in a 96-well optical-bottom microplate (Greiner Bio-One, Frickenhausen, Germany) using a Celigo Imaging Cell Cytometer (Nexcelom Bioscience, Lawrence, MA). Cells were identified using the blue channel (Hoechst-positive cells), and the green channel (FITC SNA-positive cells) was used to detect cells with alpha-2,6-sialic acid linkage. A Hoechst/FITC SNA-stained CHO-S WT sample was gated to distinguish between FITC-positive and FITC-negative cells.

2.8 Batch cultivation: cell growth analysis and N-glycosylation profiling

For batch cultivation and N-glycan analysis, cells were seeded at 0.4×10^6 cells/mL in 250 mL Corning vent cap shake flasks (Sigma-Aldrich, St. Louis, MI) as duplicates in 60 mL CD CHO medium supplemented with 1 μ L/mL anti-clumping agent (Life Technologies). CHO-S WT and non-producing parental 10x KO cell lines were additionally supplemented with 8 mM L-glutamine. *rhA1AT/rhC1INH* producing clones were cultivated in L-glutamine-free medium at all times and passaged in medium containing 25 μ M MSX until the batch cultivation was initiated. Cell densities and viabilities were determined once per day using the NucleoCounter NC-250 Cell Counter (ChemoMetec) until the viability was <70%, at which point the culture was terminated. Supernatant samples with total secreted protein (secretome) from CHO-S WT and parental, non-producing 10x KO cell lines were taken five days after seeding and pooled within biological replicates. The volume for secretome samples was calculated to harbor 20×10^6 cells. For all shake flasks, additional supernatant samples were taken by centrifuging 1 mL of cell suspension for 5 minutes at 1000 g and storage of supernatant at -80°C until further analysis.

2.9 *rhA1AT* and *rhC1INH* purification

rhA1AT and *rhC1INH* were purified using CaptureSelect affinity resins (Thermo Fisher Scientific) according to the manufacturer's instructions. *rhA1AT* was further purified by size exclusion chromatography on a Superdex 200 increase 10/300GL column (GE Healthcare) equilibrated in PBS.

2.10 Titer assessment of *rhA1AT/rhC1INH* producing clones

rhA1AT and *rhC1INH* titers were determined using biolayer interferometry on an Octet RED96 (Pall, Menlo Park, CA, USA) as described previously for A1AT [39]. After hydration in PBS, streptavidin biosensors (18-5021, Fortebio, Pall) were functionalized with CaptureSelect biotin anti-A1AT conjugate or CaptureSelect biotin anti-C1INH conjugate (Thermo Fisher Scientific) at 5 μ g/mL in PBS, and blocked in PBS containing 1 μ g/mL biocytin (600 and 300 s incubation steps, respectively). Standards were prepared in spent

CHO-S medium using plasma-derived A1AT (Athens Research & Technology) at 100, 50, 25, 12.5, 6.3, 3.1, and 1.6 µg/mL or C1INH (R&D systems) at 40, 20, 10, 5, 2.5, 1.25, and 0.625 µg/mL. Samples and standards were diluted two-fold and contained 0.1% BSA w/v, 0.1% tween-20 v/v, and 500 mM NaCl. When needed, samples were further diluted to fall within the range of the standard dilution series. After equilibration in spent CHO-S medium (120 s), samples and standards were measured for 300 s with a shaking speed of 1000 rpm at 30°C. Regeneration was performed with 50 mM TRIS, 2 M MgCl₂, pH 7.5. Assays were performed in 96-well black microplates (Greiner Bio-One, Kremsmünster, Austria). Octet System Data Analysis 7.1 software was used to calculate binding rates and absolute A1AT and C1INH concentrations.

2.11 SDS-PAGE, isoelectric focusing and PNGase treatment

SDS-PAGE was performed on Novex 4-12% Tris-Glycine mini gels and isoelectric focusing (IEF) was performed on Novex pH 3-10 IEF gels (Thermo Fisher Scientific) as per the manufacturer's instructions. Deglycosylation with PNGase F was performed according to the manufacturer's instructions (New England Biolabs, Ipswich, MA).

2.12 Activity assays

A1AT inhibitory activity was determined using the EnzChek Elastase Assay Kit (Molecular Probes, Eugene, OR) according to the manufacturer's instructions. In short, A1AT (8.0, 4.0, 2.0, 1.0, 0.5, 0.25, 0.13, and 0.06 µM) was incubated with purified active porcine pancreatic elastase and fluorescently labelled substrate (DQ-elastin). Measurement of fluorescence was performed after 45 min at room temperature (Excitation: 485 nm, slit width 9.0 nm; Emission: 530 nm, slit width 13.5 nm).

C1INH inhibitory activity was determined using the Technochrom C1INH Assay Kit (TechnoClone, Vienna, Austria). In short, plasma containing C1INH activity (120%, 60%, 30%) and samples (~0.25 µM) were incubated with substrate-buffer mixture for 3 min at

room temperature, after which 50% acetic acid was added. Extinction was measured at 405 nm.

2.13 N-Glycan analysis

N-glycans were derivatized with GlycoWorks RapiFluor-MS N-Glycan Kit (Waters, Milford, MA) according to the manufacturer's instruction. Briefly; 12 µg purified protein or 12 µl of 10x concentrated (Amicon Ultra-15, Merck) secretome sample was used for each sample. Labeled N-Glycans were analyzed by LC-MS as described previously [33]. Separation gradient from 30% to 43% 50 mM ammonium formate buffer and MS were run in positive mode. Amount of N-Glycan was measured by integrating the peaks with Thermo Xcalibur software (Thermo Fisher Scientific, Waltham, MA) giving the normalized, relative amount of the glycans.

2.14 Proteomics

Preparation of protein extract from CHO cells were done as previously described in Bonde et al., 2016 [40]. Liquid chromatography was performed on a Cap-LC system (Thermo scientific) coupled to an 75 µm x 15 cm 2µm C18 easy spray column (Thermo Scientific). The flow rate 1.2 ul and using a stepped gradient, going from 4% to 40% acetonitrile water over 50 minutes. The samples were sprayed into an Orbitrap Q Exactive HF-X mass spectrometer (Thermo Scientific). MS-level scans with resolution set to 60,000; Data dependent MS2 selection with HCD collision energy set to 28%. The resulting data were analyzed using MaxQuant. Data was searched against the Chinese hamster database retrieved from Uniprot with proteome Id UP000001075.

3 Results

3.1 Growth profile and N-glycan profile of clonal 10x KO cell lines

The aim of our study was to produce *rhA1AT* and *rhC1INH* in CHO cells with N-glycan profiles similar to human *pA1AT* and *pC1INH*. Our approach was to engineer the heterogeneous N-glycan profile of CHO-S WT cells towards a homogeneous A2G2S2 N-glycan structure, which is the predominant N-glycan on *pA1AT*/*pC1INH*. To this end, we generated out-of-frame insertions or deletions (indels) in eight glycosyltransferase genes (*Mgat4A*, *Mgat4B*, *Mgat5*, *St3gal3*, *St3gal4*, *St3gal6*, *B3gnt2*, *Fut8*) as well as in the genes *Sppl3* and *Glul* (Suppl. Table S4) over four successive rounds of multiplexed CRISPR/Cas9 gene editing. Two clones with indels in the targeted genes were subjected to growth analysis and N-glycan profiling.

Two clones (10x KO A and 10x KO B) with out-of-frame indels in all ten gene targets were obtained and both showed a pronounced increase in batch culture longevity when compared to the parental CHO-S WT cell line (Fig. 1A).

Fig. 1: Growth and N-glycan structure analysis of CHO-S WT and 10x KO cell lines. (A) Viable cell density (VCD) and viability of batch cultures of CHO-S WT and two clonal cell lines (10x KO A and 10x KO B) with indels in eight glycosyltransferases as well as Glul and Sppl3. Error bars indicate the standard deviation of triplicate parallel cultures. (B) N-glycan profiling of total secreted proteins from CHO-S WT and the 10x KO A and 10x KO B clones. In the chromatogram, elution time indicated on the x-axis and y-axis represents signal intensity normalized to highest peak. (C) Proportion of non-fucosylated, biantennary N-glycans with terminal galactose (A2G2) in total secreted proteins from CHO-S WT and the 10x KO A and 10x KO B clones.

CHO-S WT reached maximal viable cell density of $\sim 6 \times 10^6$ cells/mL on day five and cell viability declined rapidly to <50% on day 6. In contrast, the 10x KO A and 10x KO B clones had cell viabilities >75% until day 10 of the batch cultivation and reached higher maximal viable cell density than CHO-S WT.

N-glycan analysis of the CHO-S WT secretome resulted in more than 25 annotated N-glycan structures (Fig. 1B) where the A2G2S2 structure, predominantly found on *p/A1AT* and *p/C1INH*, was not detected. The majority of CHO-S WT N-glycans contained core-fucosylation. The N-glycans produced by CHO-S WT cells appear diverse and comprise high-mannose structures as well as non-galactosylated, fully and partially sialylated di-, tri- and tetra-antennary structures (all with alpha-2,3-linked sialic acids). A2FG2S2 was found as the main N-glycan on total secreted proteins of CHO-S WT. In contrast, the N-glycan profiles of 10x KO A and 10x KO B are more homogeneous (Fig. 1B) with all structures lacking core-fucosylation. In addition, only relatively small amounts of CHO-specific alpha-2,3-linked sialylation were present.

After disruption of the targeted genes, the proportion of A2G2 within N-glycan structures of total secreted proteins was increased from 3.5% (CHO-S WT) to 79% in both 10x KO clones (Fig. 1C). We concluded that the 10x KO A and B clones were suitable host cell lines in our effort to generate humanized N-glycans.

3.2 Introducing human-like sialylation in 10x KO cell lines

On the basis of A2G2 secretome N-glycan structures of clone 10x KO B, we aimed to develop clonal cell lines expressing ST6GAL1 and *rhC1INH* or ST6GAL1 and *rhA1AT*. We envisioned that such cell lines are capable to produce *rhA1AT* or *rhC1INH* with predominant A2G2S2 N-glycan structures as found on *p/A1AT* and *p/C1INH*. The functional Glul-KO selection system was confirmed by MSX-dosage dependent recovery times of cell viabilities from transfected cell pools (Suppl. Fig. 3A). Passaging of the different

transfection pools was performed until viability and doubling times were stable. We then conducted FACS-based single cell cloning with the 50 μ M MSX-selected cells. During the expansion of the generated clones, only clones exhibiting predominant FITC-SNA staining and detectable levels of *rhA1AT*/*rhC1INH* in supernatants on coomassie-stained SDS-PAGE gels were selected (Suppl. Fig. 2). Based on these criteria, two *rhA1AT* (A1-1 and A1-2) and two *rhC1INH* (C1-1 and C1-2) producing clones were selected for further characterization.

SNA lectins are reported to bind predominantly to sialic acids of N-glycans linked to the galactose residue in a human-like alpha-2,6-sialylation. Analyzing FITC-SNA-stained CHO-S WT, we found relatively low levels of alpha-2,6-sialylation (Fig. 2A). To determine the proportion of cells with human-like sialylation, FITC-SNA stained CHO-S WT samples were used to gate between FITC-positive and FITC-negative cells (Suppl. Fig. 2A). Within the two 50 μ M MSX-selected polyclonal cell lines, <30% of the cells were found to comprise alpha-2,6-linked sialic acids on N-glycans of cell surface proteins (Fig. 2B). In comparison, 82-90% of the cells in the populations of the selected four clones (A1-1, A1-2, C1-1 and C1-2) had the desired alpha-2,6-linked sialic acids on their N-glycans.

Fig. 2: FITC-SNA lectin staining of selected poly- and monoclonal cell lines. (A) Fluorescent images of CHO-S WT and A1-1 cell line. Cells were stained for alpha-2,6-sialic acid linkage with FITC-SNA (green) and for nuclei with Hoechst (blue). The bottom right corner bar displays a length of 500 μ m (B) Comparison of FITC-SNA positive cells. FITC-SNA lectin staining of CHO-S WT, two 50 μ M MSX polyclonal cell lines and four selected clones. Bars indicate the proportion of cells with positive FITC signal due to SNA lectin binding on alpha-2,6-linked sialic acids on the cell surface. Error bars represent standard deviation of three individual measurements per sample.

3.3 Extended culture longevity retained in *rhA1AT* and *rhC1INH*-producing clones

Both the two *rhA1AT*- and the two *rhC1INH*-producing clones showed the extended culture longevity as well as maximum VCD similar to the parental 10x KO B cell line (Fig. 3A). Viabilities of all clones were >75% until day 9 and clone C1-2 maintained cell viability >75% until day 11, similar to the non-producing parental 10x KO B.

In both *rhC1INH*-producing clones, *rhC1INH* titers increased from day 0 until day 5, but then stagnated at ~40 µg/mL until the end of the batch cultures (Fig. 3B). In comparison, *rhA1AT* titers from clones A1-1 and A1-2 increased continuously to 123 µg/mL and 117 µg/mL, respectively. Despite increasing numbers of viable cells, the stagnation of C1INH titers at ~40 µg/mL for clones C1-1 and C1-2 in the second half of the batch cultures leads to the assumption that *rhC1INH* is unstable in the cell culture. By SDS-PAGE gel analysis of late phase supernatant samples we observed protein bands migrating just below *rhC1INH* (~70-100 kDa) which were not present in the non-producing parental clone (Suppl. Fig. 4A).

Fig. 3: Growth profiles, product titers and specific productivities of selected producing and non-producing clones. (A) Viable cell densities and cell viabilities of CHO-S WT, 10x KO B the *rhA1AT*- (A1-1 and A1-2) and *rhC1INH*- (C1-1 and C1-2) producing clonal cell lines

measured in batch cultures. Error bars indicate range of duplicate parallel cultures. (B) *rhA1AT* and *rhC1INH* titer in supernatants during the batch culture experiment. Error bars indicate standard deviation of three individual measurements from two shake flasks per clone. (C) Specific productivities of the *rhA1AT* and *rhC1INH*-producing clonal cell lines in the batch culture experiment. Average specific productivity was calculated from day 2 – 5 and from day 6 – 9. Colored symbols represent average measured specific productivity for shake flask duplicates. Black lines shows the average specific productivity based on the three measurements of shake flask duplicates.

On the basis of *rhA1AT*/*rhC1INH* concentration in the cultivation supernatant and integral of viable cells (IVC), we determined the average specific productivity of the four clones during day 2 – 5 and day 6 - 9 (Fig. 3C). In the early phase, the specific productivity of *rhA1AT* for clones A1-1 and A1-2 was 5.8 and 4.0 pg/cell*day, respectively, decreasing to 2–3 pg/cell*day in the late phase (day 6–9). On the contrary, the two *rhC1INH*-producing clones expressed *rhC1INH* at ~5 pg/cell*day in the early phase, whereas their specific productivity in the late phase decreased to ~0 pg/cell*day. Overall, cell growth of all four clones was comparable to the parental cell line whereas product titers of A1AT-producing clones were increased compared to C1INH-producers.

3.4 Activity and N-glycosylation profile of CHO-produced *rhA1AT* and *rhC1INH* are similar to plasma-derived products

We purified and characterized *rhA1AT* and *rhC1INH* to investigate the impact of our N-glycosylation engineering approach on product quality and protein activity. Therefore we compared the protein products produced in clonal cell lines derived from 10x KO B (*rhA1AT* and *rhC1INH*) to the CHO-S WT and plasma-derived counterparts (*pA1AT* and *pC1INH*).

SDS-PAGE gel analysis revealed that purified *rhA1AT* and *rhC1INH* produced in the four clones seem to have hydrodynamic volumes (molecular weight) similar to *pA1AT* and *pC1INH* without detectable impurities as seen in *pC1INH* (Fig. 4A). *rhA1AT* and *rhC1INH* produced in CHO-S WT background did not co-migrate with *pA1AT* and *pC1INH*,

respectively. However, after deglycosylation with PNGaseF, all recombinantly produced proteins aligned with corresponding bands of *p/A1AT* and *p/C1INH* with the exception of *rhC1INH* produced in a CHO-S WT background displayed an additional protein band at ~65 kDa.

Fig. 4: Characterization of purified *rhA1AT* and *rhC1INH*. (A) SDS-PAGE gel analysis of commercially available Cinryze (*p/C1INH*) and Prolastin-C (*p/A1AT*) as well as *rhA1AT* and *rhC1INH* purified from polyclonal CHO-S WT or from monoclonal cell lines derived from 10x KO B. Removal of N-glycans by PNGaseF was performed where indicated. PNGaseF migrating as a ~40 kDa band is indicated with an asterisk and impurities of *p/C1INH* are indicated with arrows. (B) IEF gel analysis of same proteins as described for panel A. 2.5 µg purified protein was analysed per sample if not indicated otherwise. (C) N-glycan structures annotated from *rhA1AT* and *rhC1INH* produced in clones A1-1 and C1-1. (D) Left panel: *In vitro* assay measuring the inhibition of elastase activity at different concentrations of *p/A1AT* and *rhA1AT* purified from clones A1-1 and A1-2. Error bars indicate range of duplicate measurements. Maximum proteolytic activity of porcine elastase was set to 100%. Right panel: *In vitro* activity assessment of *p/C1INH* and *rhC1INH* purified from clones C1-1 and C1-2. As described in the assay, 1 IU/ml C1INH activity was set to 100%. Error bars indicate range of duplicate measurements.

To further characterize the CHO-produced *rhA1AT* and *rhC1INH*, we performed IEF gel analysis (Fig. 4B). *rhA1AT* from clones A1-1 and A1-2 manifested in two bands with isoelectric points (pI) at ~ pH 4.5 similar to *p/A1AT*. In contrast, *rhA1AT* produced in a CHO-S WT background displayed more than nine detectable isoforms with pI between pH 4 – 5.

IEF gel analysis of *rhC1INH* produced in a CHO-S WT background resulted in isoforms with pI ranging from pH ~4 – 5.5. A high degree of heterogeneity was also found in purified *rhC1INH* produced in clone C1-1. However, *rhC1INH* produced in clone C1-2 was less heterogeneous with pI at pH ~3.5 similar to *p/C1INH*.

In N-glycan analysis of purified *rhA1AT* and *rhC1INH* from CHO-S WT cells we detected a higher degree of heterogeneity compared to N-glycan structures on *rhA1AT* and *rhC1INH* from polyclonal 10x KO cell pools (Suppl. Fig. 3B). The polyclonal cell lines revealed two predominant sugar structures on both proteins (A2G2 and A2G2S2 N-glycans), whereas we could not detect the A2G2S2 structure on products from CHO-S WT. Moreover, the amount of predominant N-glycan structures on *rhA1AT* and *rhC1INH* was decreased from two (polyclonal pools) to one (monoclonal producers), identified as A2G2S2 N-glycan (Fig. 4C).

All four 10x KO-derived monoclonal cell lines produced *rhA1AT* and *rhC1INH* with higher proportion of A2G2S2 structures than *plA1AT* and *plC1INH* (Suppl. Fig. 2C and Suppl. Fig. 3C). The proportion of A2G2S2 in *rhA1AT* and *rhC1INH* was approximately 88 - 92% and 84%, respectively, and 82% for *plA1AT* and 66% for *plC1INH*.

Finally, we investigated the activity of purified *rhA1AT* and *rhC1INH*. *rhA1AT* activity was determined by its inhibitory function of elastase activity (Fig. 4D, Suppl. Fig. 4B). Similar to *plA1AT* and *rhA1AT* from CHO-S WT, a decrease in elastase activity was detected at A1AT concentrations $>0.1 \mu\text{M}$ for *rhA1AT* from clones A1-1 and A1-2. In addition, 50% of elastase inhibition was reached at $\sim 0.3 \mu\text{M}$ A1AT for *plA1AT* as well as *rhA1AT*. *In vitro* activity of purified *rhC1INH* produced by clones C1-1 and C1-2 was similar or higher compared to *plC1INH*.

4 Discussion

We aimed to produce *rhA1AT* and *rhC1INH* in CHO-S with N-glycan profiles similar to *plA1AT* and *plC1INH*, which to our knowledge has not yet been achieved by recombinant expression. First, the heterogeneous N-glycan profile of CHO-S WT cells was changed to more homogeneous profiles in bespoke cell lines with predominant A2G2 N-glycan structures (Fig. 1B). Disrupting nine N-glycosylation-related genes increased the A2G2 proportion on total secreted protein from 3.5% in CHO-S WT-derived cells to $\sim 80\%$ in 10x KO cell lines (Fig. 1C). This supports the previously suggested strategy to decrease N-glycan branching and alpha-2,3-sialylation by disrupting *Mgat4A*, *Mgat4B*, *Mgat5*, *St3gal3*, *St3gal4* and *St3gal6* [34]. The impact of gene disruptions on cell culture performance was assessed in batch cultures. Interestingly, the monoclonal cell lines with disruption in ten gene targets showed enhanced growth characteristics compared to CHO-S WT cells (Fig. 1A). Overexpression of the *Glul* gene has previously been found to decrease ammonia levels, which might explain improved CHO cell growth of the four characterized producer

clones in L-glutamine-free medium [39]. However, the cause for the boosted cell growth of Glul-lacking 10x KO cell lines in L-glutamine-supplemented medium (Fig. 1A) remains to be explored in further studies. Additionally, when CHO-S cells are subjected to a single cell sorting-based selection procedure, we suspect that the protocol generates monoclonal cell lines with an extended culture longevity phenotype compared to the parental cell line. Thus, we do not suggest that knocking out the 10 gene targets lead to the observed extended culture longevity phenotype.

Since the disruption of the ten targets did not seem to interfere with cell culture performance, we performed co-expression of ST6GAL1 and *rhA1AT* or ST6GAL1 and *rhC1INH* in the 10x KO-derived clone B. After transfection, we observed a MSX-concentration dependent recovery of the transfected cell pools and successful killing of untransfected 10x KO B after 5 days of growth in L-glutamine-free medium similar to a previous study (Suppl. Fig. 3A) [41]. However, untransfected CHO-S WT cells were also able to recover up to the highest MSX-concentration of 50 μ M, which is in accordance to previous work [36]. As shown in the killing curve of the untransfected 10x KO cells, the advantage of the Glul-KO system here seems to be the elimination of untransfected cells.

Surprisingly, after selection at 50 μ M MSX, the polyclonal cell lines did not show the desired predominant A2G2S2 glycosylation of purified *rhA1AT* and *rhC1INH* as we found incomplete sialylation on both proteins (Suppl. Fig. 3B). Similar lack of sialylation in the polyclonal cell lines was found after FITC-SNA lectin staining where only <30% of cells were identified to have alpha-2,6-sialylation (Fig. 2B). This might be due to incomplete vector integration into the genomic DNA or chromosome instability leading to a heterogeneous cell population with reduced stability of the integrated elements as reported earlier [42]. The cell pools most likely harbor a mixture of cells which do not all express the ST6GAL1-protein successfully. However, we were able to discard clones with

incomplete sialylation by single cell cloning and screening for FITC-SNA lectin positive clones producing *rhA1AT* or *rhC1INH*.

Although the stagnating *rhC1INH* titer at day 5, the reported *rhC1INH* titer here is higher than previously reported production platforms with maximum titers of only 6 µg/mL in insect cells [29] and 30 µg/mL in *P. pastoris* [27] albeit the media we used was without any optimization for protein production. Further investigation needs to be carried out to understand the stagnation of *rhC1INH* titers. However, it can be speculated that the rate of *rhC1INH* production is similar to the rate of *rhC1INH* degradation, preventing an increase of *rhC1INH* titer in the cultivation supernatant. In comparison to *pC1INH* (Cinryze), the *rhC1INH* from C1-1 and C1-2 did not show α1-antichymotrypsin, ceruloplasmin and Factor C3 impurities on SDS-PAGE gels [8] (Fig. 4A), implying that CHO-based cell platforms possibly can supply HAE-C1INH patients with higher purity than human plasma.

With titers between 300 – 400 µg/mL, human neuronal cell lines produce *rhA1AT* with higher titers than our clones A1-1 and A1-2. However, *rhA1AT* from these neuronal cells exhibits core-fucosylation, is not fully sialylated, and therefore differs largely from *pA1AT* N-glycosylation [24]. Similarly, earlier studies expressed *rhA1AT* in CHO with titers of up to 1.15 g/L, though differing from *pA1AT* by revealing core-fucosylation and alpha-2,3-sialylation [25, 26, 43].

In contrast to the production platforms listed earlier, *rhA1AT* and *rhC1INH* produced in our 10x KO cell lines are not only exceeding sialylation levels of *pA1AT* and *pC1INH* (Suppl. Fig. 2C), but also reveal human-like alpha-2,6-sialylation instead of alpha-2,3-sialylation. Previous work reported only 2.6% A2G2S2 structures on *rhA1AT* expressed in CHO-K1, however with 2,3- sialic-acid linkage [26].

Interestingly, the increased sialylation of *rhA1AT* from the two clones had no impact on *in vitro* activity (Fig. 4D). This is in accordance with previous work, which showed that A1AT

activity is not linked to its N-glycosylation and CHO WT produced *rhA1AT* has similar activity to *pA1AT* [10, 38]. Furthermore, differences of CHO-S WT- and 10x KO-derived *rhA1AT* were made visible using IEF gel analysis, where *rhA1AT* from the two clones revealed similar patterns to *pA1AT* (Fig. 4B).

As presented in Fig. 4B, in contrast to *rhA1AT*, *rhC1INH* differed partially in IEF gel analysis profile from *pC1INH*. Increased *rhC1INH* sialylation (Suppl. Fig. 2C) might lead to altered charge distribution and consequently cause changes in IEF gel patterns. For *rhC1INH* from clone C1-1, we observed a double-band in SDS-PAGE analysis although N-glycans were removed by PNGaseF treatment (Fig. 4A). This might indicate that O-glycan charge variants are responsible for the heterogeneity observed in IEF gel analysis and SDS-PAGE of *rhC1INH* from C1-1 (Fig. 4A and 4B) as described previously [44].

In summary, our work describes a strategy to successfully engineer the heterogeneous N-glycosylation profile of CHO-S WT cells to the specific A2G2S2 N-glycan structure with the purpose of producing *rhA1AT* and *rhC1INH* with N-glycan profiles similar to human plasma-derived products. We used CRISPR/Cas9 to disrupt ten genes and then overexpressed *rhA1AT* or *rhC1INH* on a ST6GAL1- and Glul-encoding plasmid. After selection with MSX and single cell cloning, we identified clones expressing *rhA1AT* or *rhC1INH* with titers of up to 124 µg/mL and 42 µg/mL, respectively (Fig. 3B). Purified *rhA1AT* and *rhC1INH* were similar to the plasma-derived counterparts judged by SDS-PAGE analysis (Fig. 4A), degree and type of sialylation (Fig. 2B, Suppl. Fig. 2C, Suppl. Fig. 3C) and *in vitro* activity (Fig. 4D). Thus, the work presented shows the promise and potential of replacing cost-intensive and possibly unsafe plasma-derived augmentation therapy for AATD and C1INH-HAE patients by CHO- produced *rhA1AT* and *rhC1INH*. This strategy is in compliance with the Medical and Scientific Advisory Council (MASAC) recommendation of replacing plasma-derived products with recombinant products for treatment of diseases [45].

A

B

Suppl. Fig. 1: Vector design for overexpression. (A) *rhC1INH* and *ST6GAL1* are under the control of mCMV-hEF-1a-5' consisting of an mCMV enhancer element, a hEF-1a promoter element, and a 5' HTLV untranslated region. The plasmid backbone consists of an ampicillin resistance cassette and SV40 early promoter in front of the Glul (GS) sequence. Poly-A sequences (purple) terminate Glul, *rhA1AT* and *rhC1INH* cassettes. (B) *rhA1AT* and *ST6GAL1* are under the control of mCMV-hEF-1a-5'. The plasmid backbone consists of an ampicillin resistance cassette and

SV40 early promoter in front of the Glul (GS) sequence. Poly-A sequences (purple) terminate Glul, *rhA1AT* and *rhC1INH* cassettes.

Suppl. Fig. 2: Screening for FITC SNA positive and *rhA1AT* producing clones. (A) Supernatant of monoclonal cell lines (clone 1 - 5) on SDS PAGE to screen for *rhA1AT* producing clones. Control samples consist of pA1AT and supernatant from non-producing CHO-S WT cells. (B) Cells of CHO-S WT, the 50 μ M MSX A1AT polyclonal cell line and the clones A1-1 and A1-2 were stained with FITC-SNA. The histograms show the number of cells on y-axis and FITC mean intensity on the x-axis. CHO-S WT cells were used for gating between FITC-positive and -negative cells (red line). (C) N-glycan analysis of purified A1AT and C1INH versions. A2G2S2 proportions of purified *rhA1AT* and *rhC1INH* from different clones compared to pA1AT and pC1INH.

Suppl. Fig. 3: Viability of cells during MSX-based selection and N-glycan analysis of A1AT and C1INH derived from plasma as well as polyclonal and monoclonal cell lines. (A) Cell viability of non-transfected and transfected cell lines during selection with different concentrations of MSX. (B) N-glycan histograms of purified A1AT and C1INH from transiently transfected CHO-S WT and 50 μ M MSX-selected polyclonal cell lines in comparison to Cinryze and Prolastin-C. (C) N-glycan

A

Western blot analysis of elastase activity. The blot shows protein bands across two panels. The left panel shows the effect of pC1INH concentrations (0, 8.75, 17.5, 35, 70 $\mu\text{g/ml}$) on elastase activity. A band at approximately 100 kDa is marked with an asterisk (*). The right panel shows the effect of 10x KO B and C1-1, C1-2 on elastase activity. Molecular weight markers (250, 130, 100, 70, 55, 35 kDa) are indicated on both sides.

B

Graphs showing elastase activity and C1INH activity.

Left graph: Elastase activity [%] vs. [A1AT] (μM). The graph shows the inhibition of elastase activity by A1AT. The legend indicates: CHO-S WT (open circles), pA1AT (filled circles), A1-1 (open triangles), and A1-2 (filled triangles). The activity decreases sharply as [A1AT] increases from 0.1 to 1 μM .

Right graph: C1INH activity [%] bar chart. The chart shows the relative C1INH activity for CHO-S WT, pC1INH, C1-1, and C1-2. The activity is highest for C1-2 (approx. 115%) and lowest for CHO-S WT (approx. 60%).

35

Table S1: sgRNA target sequences. The bases in red mark the PAM site

Gene name of target	hypothesized KO effect	Target sequence (5'→ 3')
MGAT4A	decreased branching	GTCTACATTCGTCACCTGTCG GGG

Table S6: Proteomics-based identification of proteins in whole cell lysates from CHO KO and CHO WT cells. Of the KO's only Glul could be detected. KO of Glul is verified as no hits in KO cell line.

Protein IDs	Fasta headers	Intensity 10x KO cell line_1	Intensity 10x KO cell line_2	Intensity WT_1	Intensity WT_2
