Abstract: (Your abstract must use Normal style and must fit in this box. Your abstract should be no longer than 300 words. The box will ‘expand’ over 2 pages as you add text/diagrams into it.)

Preparation of Your Abstract
1. The title should be as brief as possible but long enough to indicate clearly the nature of the study. Capitalise the first letter of the first word ONLY (place names excluded). No full stop at the end.
2. Abstracts should state briefly and clearly the purpose, methods, results and conclusions of the work.

Introduction: Clearly state the purpose of the abstract
Methods: Describe your selection of observations or experimental subjects clearly
Results: Present your results in a logical sequence in text, tables and illustrations
Discussion: Emphasize new and important aspects of the study and conclusions that are drawn from them
Abstract. Over 50% of the anthropogenic nitrous oxide (N₂O) emission in the UK derives from agriculture, thereby requiring the use of more effective fertilisers. Green microalgal cultivation on wastewater resources was investigated due to its potential for nutrients and water recovery for agricultural crops production (slow-leaching fertiliser and irrigation water). Algal cells are able to store nitrogen and phosphorus in-excess, thus effectively conveying nutrients to crops, which in turn can reduce the fraction of nutrients contributing to (a) diffuse water pollution and (b) greenhouse gas emission. Main objectives: (i) presenting the biogeochemical process framework for microalgal cultivation for crops production; (ii) assessing the effect of feedstock nutrient composition on microalgal culture composition; (iii) assessing microalgal kinetics, and evaluating dynamic fertilisation potential; (iv) proposing process operation and control for photobioreactors for fertigation. The impacts of dynamic, optimum, influent N-to-P ratio (NPR) on microbial community stability, stored nutrient quotas, and algal biokinetics were assessed. We used continuous laboratory-scale reactors to cultivate a mixed green microalgal culture (Chlorella sp. and Scenedesmus sp.) and a monoculture of Chlorella sp. with high capacities of luxury nutrient uptake from treated wastewater. Decreasing influent NPR can compromise mixed culture stability by the proliferation of diatoms (with reduced nutrient storage capacity) - detected in the influent treated wastewater (Fig. 1). Optimal culture composition was restored by resetting feedstock composition to optimal NPR range.

Fig. 1  
Chlorella monoculture, challenged by varying influent NPRs kept stable throughout long-term cultivation. ASM-A simulations can accurately predict the photobioreactor performance for both mixed and monoculture using a single parameter subset, i.e. biokinetics was unaltered by varying feedstock composition.
Fig. 2
Process control design reported earlier in literature (e.g. Valverde-Pérez et al., 2016) can be used to optimize the photobioreactor performance to produce microalgae with intracellular stored nutrient content to match crops’ nutrient requirements.
