Introduction

X-ray ptychography [1] is a scanning coherent diffraction imaging (lensless) technique that provides unlimited fields-of-view for the sample reconstruction and enables reconstruction of the generally unknown illumination function [2]. In ptychography a phase-retrieval algorithm plays the role of an image-forming lens by recovering the unknown phase numerically, using iterative algorithms [3]. Here, we present ptychographic imaging under grazing incidence as a technique suitable for investigation of surface properties of thin films. The grazing incidence configuration is of special interest for the study of sparse monolayers of nanoparticles that yield weak scattering signal in a conventional transmission configuration. The proposed method has a potential for *in situ* studies of particle-substrate interactions in a gaseous environment, under elevated temperatures and will allow describing time-evolution of an inhomogeneous sample structure.

Grazing Incidence Ptychography

In grazing incidence configuration, coherent X-ray scattering from substrate-supported nanostructures is measured below the critical angle of the sample substrate.

\[ \alpha \] — incident wavevector
\[ \beta \] — scattered wavevector
\[ \gamma \] — angle of incidence
\[ \delta \] — angle of reflection

The shallow incident angle provides a high interaction cross-section with the sample because of the large footprint and the total external reflection of the incident beam from the substrate.

Figure 1: Schematic of grazing incidence ptychography.

Figure 2: (a) Beam footprint on the sample at an incident angle of 0.27°; (b) illuminated part of the Siemens star phantom with an aspect ratio of 1.

Preliminary simulations show that reconstruction of the sample can be achieved by the proposed method using modified propagation of the exit wave front from the sample plane to the detector [4].

Experimental results

The experiment was performed at the cSAXS beamline of the Swiss Light Source (SLS) facility in Switzerland. Figure 4 shows part of a Siemens star phantom that corresponded to the imaged area used for ptychographic reconstruction along with an amplitude of the reconstructed Siemens star and reconstructed illumination function [5]. (under a grazing incidence angle of 0.27 degrees, both corrected with respect to the aspect ratio of the reconstruction pixel size).

Reactor chamber for *in situ* measurements

Figure 3: Tilted plane correction of a diffraction pattern: (a) before and (b) after correction

Figure 4: (a) Scanned part of the Siemens star phantom, the white region is showing entire size of the supporting wafer, black pattern is the Siemens star with highly anisotropic resolution. (b) Reconstruction of the amplitude signal reconstructed from diffraction data from the sample corresponding to the region simulated in (a). (c) Reconstruction of the illumination function.

Future work

Future improvements to the method will include grazing incidence ptychographic tomography for achieving isotropic resolution in object reconstruction. This requires better alignment of the measured projections, higher precision in the sample motion, and a new design of the reactor chamber for *in situ* studies.

Acknowledgments

This study was supported by the Marie Skłodowska-Curie Innovative Training Network MUMMERING (Multiscale, Multimodal, Multidimensional imaging for Engineers/RING), funded through the EU research programme Horizon 2020 and by the Ministry of Higher Education and Science (DANSCATT grant, 7055-00078). The authors would like to acknowledge the support of the staff of the NanoMAX beamline at the MAX IV Laboratory, O. Carbone, A. Björling, and A. R. Fernandez and of the cSAXS beamline at the Swiss Light Source, A. Diaz. The authors thank O. Hansen, C. D. Damsgaard, and B. Ching from DTU Nanolab who provided best structures for the experiment.
