(54) Title: OPTICAL LINE TERMINAL AND OPTICAL FIBER ACCESS SYSTEM WITH INCREASED CAPACITY

Fig. 3A

(57) **Abstract:** The present disclosure relates to an optical fiber access system based on passive optical networks. In particular the present disclosure relates to a PON system with increased capacity and a method for increasing the capacity in a PON system. One embodiment relates to an optical line terminal for a passive optical network, comprising at least one transmitter for generating a time division multiplexed (TDM) downstream optical data signal, a first time lens optical signal processor configured to convert the downstream TDM signal to a downstream WDM signal for distribution to a plurality of users, and at least one receiver for receiving and processing an upstream signal from said users.

Optical line terminal and optical fiber access system with increased capacity

The present disclosure relates to an optical line terminal that can be used in an optical fiber access system based on passive optical networks. The present disclosure further relates to a PON system with increased capacity and a method for increasing the
5 capacity in a PON system.

Background of invention

The incessant rise in data consumption by both fixed and mobile broadband subscribers drives continuous industry innovation to meet this challenge. Optical fiber access systems based on passive optical networks (PON) are currently being deployed
10 on a mass market scale by numerous network operators. PON systems are often referred to as the "last mile" between an internet service provider and an individual user, i.e. PON systems are typically used to provide fiber to the end consumer, normally using a point-to-multipoint architecture, wherein unpowered fiber optic splitters can be used to enable a single optical fiber to serve multiple end-points. The end-
15 points are often individual users rather than commercial distributors.

Passive optical networks are "passive" in the way the networks typically do not use electrically powered components to split the signal. Instead, the signal is distributed using beam splitters. Each splitter typically splits the signal from a single fiber into 16,

20 32, or up to 256 fibers, depending on the manufacturer, and several splitters can be aggregated in a single cabinet. A beam splitter cannot provide any switching or buffering capabilities and does not use any power supply. Passive optical networks have both advantages and disadvantages over active networks. The complexities involved in keeping electronic equipment operating outdoors can be avoided. PON

25 systems also allow for analog broadcasts, which can simplify the delivery of analog television. However, because each signal must be pushed out to everyone served by the splitter the requirements to the single downstream transmitter in the central office are high. The drivers behind PON systems nowadays are therefore high reliability, low cost, and passive functionality.

30

A PON can be based on Time-Division Multiplexing (TDM) that implements a point-to-multipoint architecture wherein the single downstream transmitter, referred to in here as an Optical Line Terminal (OLT), transmits data frames to all connected Optical

Network Units (ONUs) over a shared optical fiber network. ONUs only see their own data through the address labels embedded in the signal. In the upstream direction, the OLT schedules ONU transmissions to avoid collisions between ONUs. A passive optical splitter/combiner enables the fiber to be divided to reach multiple customer locations, thereby keeping the optical distribution network passive, cf. figs.1 and 2 where prior art PON systems are illustrated.

Passive optical network is therefore becoming the dominating technology in optical fibre access systems and fiber-to-the-home. Even though optical fibers have large bandwidth, current PON technology will run out of capacity in 4-5 years due to:

- Growing number of subscribers
 - Growing number of connected devices per subscriber
 - Increasing bandwidth demands per device or application
- Increasing the serial bitrate beyond 10 Gb/s of PON systems is difficult due to lower dispersion tolerance and the lower signal to noise ratio (SNR). This limits the maximum reach in the C-band of the dispersion uncompensated 25 Gb/s PON to 24 km and of 40 Gb/s PON to 10 km even with the dispersion tolerance enhanced duo-binary modulation [2]. Recently, ITU-T defined the second next generation PON (NG-PON2) standard for PON beyond 40-Gb/s, in which time and wavelength division multiplexed (TWDM) PON has been considered as the primary solution. A baseline TWDM-PON with 40 Gb/s aggregate capacity over 60 km SMF has been demonstrated [3]. The key challenge for TWDM-PON is to realize its optical network unit (ONU) at low cost, the cost is predicted to be more than 20 times that of a standard GPON (Gigabit-PON) ONU [1]. Another competitive candidate for NG-PON2 is the point-to-point (P2P) WDM-PON based on wavelength splitter optical distribution network, which has unique features including long reach, high bandwidth, security, high service level guarantees, easy network management and simple upgrade [4]. A major disadvantage of P2P WDM-PON is the large port count, transmitters and terminations at the central office (CO) requiring more CO space and operational cost.

Summary of invention

The present disclosure therefore presents a novel OLT structure and a novel passive optical network architecture that can drastically increase the transmission capacity of optical access systems. The novel architecture is based on the time-lens principle, i.e. time-lens optical signal processing (OSP). A time lens can expand and compress

optical pulses while substantially retaining the temporal profile of the pulse. A time lens is based on the space-time duality of light: A quadratic phase modulation (PM) of a temporal waveform is analogous to the action of a thin lens on a spatial beam, hence the expression "time lens". By combining a time lens with suitable dispersion media an optical Fourier transformation (OFT) can be realized as exemplified herein. Time lens based OFT has further been shown to be a very versatile and powerful tool for ultrafast optical signal processing. It can be applied to transfer the temporal profile of an optical signal into the frequency domain and vice-versa. The presently disclosed principle is generally based on the idea of using a time-lens based optical signal processor for optical signal conversion between time division multiplexing (TDM) and wavelength division multiplexing (WDM) - and vice versa. The capacity can be further increased by using a time-lens based optical signal processor for optical signal conversion between M-wavelength TWDM and N-wavelength WDM signals, where M typically is less than N.

15

A first aspect of the present disclosure therefore relates to an optical line terminal for a passive optical network employing the presently disclosed OLT structure. I.e. comprising at least one transmitter for generating a time division multiplexed (TDM) downstream optical data signal, and a first time lens optical signal processor configured to convert the downstream TDM signal to a downstream WDM signal for distribution to a plurality of users. Typically at least one receiver for receiving and processing an upstream signal from said users is part of the OLT as well.

I.e. in a first embodiment the time-lens based optical processor converts the TDM signal generated in the OLT into a number of WDM channels, typically of low baud rate. These can be directly demultiplexed, e.g. by a conventional passive AWG, and send to individual Optical Network Units (ONU) on the user side with a low fixed loss, typically less than 4 dB loss. At the individual ONU side, the separated WDM channel can be received by a base rate receiver, resulting in much better receiver sensitivity, typically on the order of 10 dB for 32 subscribers. This can be achieved with even lower power consumption than hitherto known. The capacity of the time-lens PON can be further increased by introducing a WDM concept.

The presently disclosed application of the time lens principle might realize approx. 10 times more data rate on optical access communication network - more cost-efficient and energy-efficient than the prior art solutions. Point to multi-point, few point to multi-

point and multi-point to multi-point schemes can be realized by applying the optical time-lens principle to PON systems.

- In particular the presently disclosed OLT structure allows generation of a large number
5 of WDM channels from a single TDM signal source, in fact the time-lens OFT approach
for PON presented herein can be tuned such that all individual signals in a TDM signal
can be converted to a specific wavelength in the WDM signal - and this can be
provided over a broad wavelength interval, such as the entire C-band (1530 to 1565
nm), L-band (1565-1 620 nm) or C+L-band or parts thereof. The frequencies of all the
10 generated WDM channels can be frequency-locked with each other, and the frequency
grid as well as the wavelength allocation can be tuned through the OFT without
separate control of all the laser frequencies as in a conventional WDM PON, i.e. rather
simply compared to conventional WDM PON.
- 15 A higher dispersion tolerance and larger power budget are also gained for long reach
PON using the presently disclosed approach. With these advantages, 40-Gbit/s PON
downstream transmission is demonstrated over 150 km 40-split unamplified SMF-plant
with a single-carrier OOK transmitter and low-cost 10-GHz APD-based receiver,
achieving a power budget of 5 1.5 dB (35.5 dB/ch.) for a BER=3x1 0⁻⁶, cf. example 1.
- 20 Meanwhile, the same system achieves 128 Gb/s PON over 100-km 64-split unamplified
fibre-plant using optical TDM technique, showing the high flexibility and scalability of
the proposed scheme in terms of wavelength control and system throughput. The
presently OLT structure and PON architecture is highly flexible in terms of wavelength
25 allocation, as it allows tuning of the signal wavelength in sub nanoseconds by encoding
(remapping) the TDM signal in time-domain, without tuning the actual wavelength of
the optical source. And each individual signal in the TDM signal can be mapped to a
specific wavelength in the WDM signal. The presently claimed invention can therefore
not only increase the capacity of PON systems, but also have the flexibility of TDM-
PON and the transmission performance of WDM-PON.
- 30 A further aspect of the present disclosure therefore relates to a passive optical network
(PON) system comprising the optical line terminal disclosed herein.
- Yet a further aspect relates to a method for generating a TDM optical signal and
35 converting it to a downstream WDM optical signal using an optical time-lens as herein
disclosed. E.g. a method for generating a downstream WDM optical signal for use in a

passive optical network system, comprising the steps of generating a time division multiplexed (TDM) signal, and converting the TDM signal to a downstream wavelength division multiplexed (WDM) signal for distribution to a plurality of users in a passive optical network by means of a first time lens optical signal processor.

5

A further aspect of the present disclosure relates to a method for generating an upstream WDM optical signal and converting it to an upstream TDM optical signal using an optical time lens as herein disclosed. E.g. a method for receiving an upstream WDM optical signal distributed from a plurality of users in a passive optical network system, comprising the steps of converting the upstream WDM signal to a time division multiplexed (TDM) optical signal by means of a second time lens optical signal processor, and demultiplexing and processing the TDM signal to individual signals.

10

Yet a further aspect relates to a method for generating a downstream TDM optical signal to a WDM optical signal using an optical time-lens as herein disclosed. A further aspect of the present disclosure relates to a method for generating an upstream WDM optical signal to an upstream TDM optical signal using an optical time lens as herein disclosed.

Detailed description of the invention

A time-lens signal processing unit comprises a dispersive medium and a phase

35 modulation stage, e.g. two phase modulation stages with an intermediate dispersion

medium, a socalled K-D-K configuration. Another example is a dispersion medium and a single phase modulation stage, a socalled D-K or K-D configuration. A time-lens signal processing stage is an example of an optical Fourier transformation (OFT). A K-D-K configuration has for example been disclosed in WO 2015/131908. However, the 5 K-D-K configuration cannot be directly applied when employing a time lens in a PON system as herein described. Instead, particular operating parameters and conditions must typically be introduced when employing a time lens in a PON system.

Time-lens principle

Just as a spatial optical imaging system can produce an image that is larger or smaller 10 than the optical object, a time lens can be used to compress or expand an optical pulse. And as previously disclosed a time lens can expand and compress optical pulses while substantially retaining the temporal profile of the pulse. A time-lens was disclosed in US 5,453,871 where a pulse compressor was presented that operated on a temporal pulse in a manner analogous to the operation of an optical imaging system.

15 The phase-modulation in the presently disclosed OFT (time-lens) module can be implemented by various means, for example by four-wave mixing (FWM), e.g. using chirped pump pulses. Four-wave mixing (FWM) can be obtained in a nonlinear optical element, wherein the nonlinear optical element is optically pumped with chirped pump 20 pulses. The nonlinear optical element may for example be a highly nonlinear fiber (HNLF). Phase-modulation can also be obtained by cross-phase modulation (XPM) using parabolic intensity profile pump pulses, or electro-optic phase-modulation using an electrical driving signal. The FWM & XPM effects typically originate from the nonlinear optical Kerr effect, which is commonly used for nonlinear optical signal 25 processing. The dispersion medium in the OFT units can be implemented by a standard fibre, such as a standard single mode fiber (SSMF) or a dispersion-compensation fibre (DCF), or a highly nonlinear fiber, or any other dispersive structure, such as Silicon-on-insulator waveguide platform. One example of the latter is an AlGaAs-on-insulator waveguide, for example a thin $\text{Al}_x\text{Ga}_{1-x}\text{As}$ layer on top of a low 30 index insulator layer residing on a semiconductor substrate. Wafer bonding and substrate removal can be used to realize the structure. The aluminium fraction (x) can for example be 17%, which makes the material bandgap 1.63 eV and the refractive index 3.33. Thanks to the large index contrast (-55%) of this layout, light can be confined in a sub-micron waveguide core. As the nonlinear parameter (γ) is highly 35 dependent on the waveguide effective mode area (A_{eff}) as expressed by $Y=2nn_2/\lambda A_{\text{eff}}$,

an ultra-high effective nonlinearity of about $660 \text{ W}^{-1}\text{m}^{-1}$, which is orders of magnitude higher than that of a typical Si_3N_4 waveguide, can be obtained for an AlGaAs-on-insulator waveguide using a cross-section dimension of 320 nm \times 630 nm [6,7].

Optical line terminal

- 5 As disclosed above a first aspect of the present disclosure relates to an optical line terminal for a passive optical network. An optical line terminal will typically comprise at least one transmitter, e.g. for generating a time division multiplexed (TDM) downstream optical data signal. A first time lens optical signal processor, i.e. an OFT element, can then be provided and configured to convert the downstream TDM signal to a
- 10 downstream WDM signal, typically for distribution to a plurality of users. At least one receiver may be provided for receiving and processing an upstream signal from said users.

In a further embodiment a second time lens optical signal processor can be provided
15 and configured to convert an upstream WDM signal received from said users to an upstream TDM signal. At least one TDM receiver can then be provided for demultiplexing and processing the upstream TDM signal. Alternatively at least one WDM receiver can be provided for demultiplexing an upstream WDM signal received from said users.

20 An optical splitter, such as a WDM coupler, can be provided for separating an upstream signal from said users / ONUs from the downstream WDM signal. At least one amplifier, e.g. an optical amplifier, such as an EDFA, can be provided for amplifying the downstream WDM signal and/or the upstream WDM signal. The downstream amplifier can be seen as a booster amplifier that boosts the WDM downstream signal before entering the transmission link. As demonstrated in example 1 herein, a 40G PON system with an unamplified transmission distance of 150 km can be obtained. Likewise with the upstream signal that can be boosted after the transmission link and before the second time lens module that converts the WDM signal to a TDM signal.

35 In one embodiment of the present disclosure the first and/or the second time lens optical signal processor comprises two phase modulation stages, preferably quadratic phase modulation stages, separated by a dispersive medium in a K-D-K configuration. Preferably $\delta\phi = K_i t^2/2$ in the first phase modulation stage with linear chirp rate K_i , $\delta\phi =$

$K_2 f/2$ in second phase modulation stage with linear chirp rate K_2 , and $D=\beta_2 i$ in the dispersion medium where β_2 is the 2nd order dispersion and L is the length, such that $K_1=K_2=VD$. The chirp rate K preferably determines the scaling factor between the time and frequency domains according to $At=2\pi A i/K$.

5

In another embodiment of the present disclosure the first time lens optical signal processor comprises a dispersive medium with dispersion $D=f_i_2 L$ followed by a phase modulation element, preferably a quadratic phase modulation element, with chirp rate $K=1/D$. The second time lens optical signal processor advantageously then comprises 10 a phase modulation element, preferably a quadratic phase modulation element, with chirp rate $K=1/D$ followed by a dispersive medium with dispersion $D=f_i_2 L$. I.e. a D-K configuration for the TDM to WDM conversion and preferably K-D configuration for the WDM to TDM conversion. Such configurations can simplify the time lens module, e.g. compared to the K-D-K configuration. The downside can be a small penalty on the 15 capacity of the system.

The dispersive medium is a length of optical fiber, such as transmission fiber, such as a standard single mode fiber (SSMF), such as a dispersion compensating fibre (DCF), such as a highly nonlinear fiber. The phase modulation stage(s) may comprise(s) a 20 length of highly non-linear fiber. In general the phase modulation can for example be based on four-wave mixing (FWM), e.g. using chirped pump pulses, cross-phase modulation (XPM) e.g. using parabolic intensity profile pump pulses, or electro-optic phase-modulation e.g. using an electrical driving signal.

25

A clock recovery unit may be provided and configured to synchronize the second time-lens signal processor to the upstream WDM signal. Further, the single channels of the upstream WDM signal may advantageously be symbol-wise synchronized at the input of the second time-lens optical signal processor. At least one control unit may be provided and connected to the transmitter and/or the receiver and configured to control 30 the wavelength and timing of the signals.

In the few point to multipoint architecture the transmitter may comprise a multi-wavelength time and wavelength division multiplexed (TWDM) array configured to generate a time division multiplexed downstream optical signal at M different 35 wavelengths, and where M is less than the number N of signal wavelengths in the

downstream WDM signal. Correspondingly the receiver may comprise a multi-wavelength time and wavelength division multiplexed (TWDM) array configured to receive and process a time division multiplexed upstream optical signal at M different wavelengths.

5

In the asymmetric (few) point to multipoint architecture the receiver may advantageously be simplified and configured to receive and process a time division multiplexed upstream optical signal at a single wavelength.

Passive optical network system

10 A further aspect of the present disclosure relates to a passive optical network (PON) system comprising the optical line terminal as described herein. A PON system typically comprises an optical fiber infrastructure for distributing the downstream and upstream signals. Typically also at least one remote node for splitting the downstream WDM signal into separate wavelength signals, typically a passive remote node, i.e.

15 without power supply, such as a passive AWG. The at least one remote node can then be configured for combining upstream separate wavelength signals into an upstream WDM signal. The remote node may comprise at least one arrayed waveguide grating (AWG) for splitting the downstream WDM signal into separate wavelength signals and/or for combining the upstream signals into a single WDM or TDM upstream signal.

20

In the symmetric point to multipoint or few point to multipoint architecture the presently disclosed PON system may further comprise separate ONU transmitters located at each user and configured to generate separate wavelength upstream signals that can be combined to a single (or few) upstream WDM signals.

25

In the asymmetric point to multipoint or few point to multipoint architecture the presently disclosed PON system may further comprise separate ONU transmitters located at each user configured to generate upstream signals at one predefined wavelength that can be combined to a single (or few) upstream TDM signal(s). In that case each

30 network line between the remote node(s) and the separate ONUs may comprise a splitter, e.g. a WDM coupler, for separating the upstream signal at said predefined wavelength from the downstream separate wavelength signals.

Symmetric point to multi-point

Figs. 3A, 3B and 4 show examples of the symmetric point to multi-point architecture. In the downstream data transmission in fig. 4 the following symbols are used:

OLT (Optical Line Terminal): PON head-end, typically located in a central office

5 **ONU** (Optical Network Unit): User side PON equipment

ODN (Optical Distribution Network) :Optical fiber infrastructure connecting OLT to ONUs

SNI(Service Node Interface): Interface to the Metro/Core Network

UNI(User Network Interface): Interface to the user network

CR (Clock recovery): to synchronize the optical signal processor 2.

10 The data signals are transmitted from the OLT (101) to N ONUs (102,103,104). A TDM transmitter (105) generates a single wavelength high speed TDM optical data signal (201) with symbol rate f_s . The TDM optical data signal is converted to an N-wavelength ($\lambda_1, \lambda_2, \dots, \lambda_N$) WDM signal (202) with channel spacing Δv using a time-lens based optical signal processor (106). The converted N-wavelength WDM signal is amplified in
15 the optical amplifier (107), and send further into a WDM coupler (108), which is used for separating the downstream and upstream signals in the OLT. A single strand fiber (109) is used for transmitting the WDM signal from the OLT to the remote node (RN) location, which is close to the ONUs. At the RN location, a passive periodic arrayed waveguide grating (AWG) (110) with wavelength channel spacing of Δv is used for
20 splitting the WDM signal to each ONU.

Fig. 5 illustrates and exemplifies the TDM (201) to N-wavelength WDM signal (202) conversion and vice-versa through the time lens signal processor (203). Here, ΔT is the symbol temporal spacing of the TDM signal, and Δv is the WDM channel spacing of the
25 converted WDM signal. The time lens optical signal processor for TDM to WDM conversion comprises two quadratic phase-modulation (PM) ($\Delta\phi = Kf/2$) stages (204, 205) with linear chirp rate K , separated by a dispersion medium (206) of $D = \beta_2 L$ (where β_2 is the 2nd order dispersion and L is the length), which satisfies the condition $K_1 = K_2 = 1/D$, i.e. it is a K-D-K configuration. The chirp rate Δf determines the scaling factor between the time and frequency domains according to $\Delta t = 2\pi\Delta f/K$. After the processor, the TDM signal is converted to a WDM signal with channel spacing Δv depending on the choice of K . The repetition frequency of the quadratic phase-modulation f_{PM} is set equal to f_s/N for TDM to N-wavelength WDM signal conversion. The symbol rate of each WDM channel also equals f_s/N . The phase-modulation (PM)
30 window is given by $T_{PM} = 1/f_{PM}$. Note that the practical process may require a short
35

guard interval (GI) between every N TDM symbols for the transition of the quadratic phase-modulation .

In the upstream data transmission , the transmitter at each ONU (102, 103, 104) generates an individual wavelength specific WDM channel ($\lambda_{v1}, A_{v2}, \dots, A_{vN}$) that matches the transmission windows of the periodic AWG (110) at a different wavelength region according to $\lambda_{vN} = \lambda_N + \Delta\lambda$. The individual WDM channels are combined to an N-wavelength WDM signal at the AWG, and transmitted back to the OLT through the same optical fiber (109) at a different wavelength region . In the OLT, the upstream WDM signal is switched to the upstream RX using a WDM coupler (108). After pre-amplification (111), the WDM signal is converted to a TDM signal using another time-lens based optical signal processor 2 (112). Fig. 5 also illustrates the N-wavelength WDM (202) to TDM signal (201) conversion through the optical signal processor 2 (112). The components and settings in optical signal processors 1 (106) and 2 (112) are basically the same. A clock recovery unit (113) is used to synchronize the time-lens signal processor 2 (112) to the WDM signal. Finally, the converted TDM signal is received by a single TDM receiver (114). Note that for WDM to TDM conversion the WDM channels typically need to be symbol-wise synchronized at the input of the time-lens processor (112), control units (115,116) are used to control the wavelength and timing of the signal in both OLT and ONU sides. Furthermore, the total time-lens PON capacity can be further increased by using optical time-division multiplexing (OTDM) in the OLT.

As stated previously the time-lens optical signal processor can be simplified from a K-D-K to a D-K configuration for TDM to WDM downstream conversion as exemplified in fig. 14. In fig. 14 this is illustrated by making the first phase modulation stage K_1 almost invisible. In case of a D-K downstream configuration it may be necessary to add a sufficient amount of guard interval (GI) in the time domain as illustrated to the left in fig. 14. The amount of guard interval is related to signal bandwidth $\Delta\lambda$ dispersion D , and the gap between the PM windows T_g , according to

$$GI \geq \frac{2\pi c}{\lambda^2} DA\lambda + T_g$$

where c is the speed of the light, A is the signal wavelength . In the C-band from about 1530 to about 1565 nm this formula can be written as

$$GI \geq 0.78 DA\lambda + T_g$$

I.e. when a sufficient guard interval is provided to the signal periodically following the repetition frequency of the quadratic phase-modulation f_{PM} , the first quadratic phase-modulation stage can be omitted as shown in fig. 14. However, adding a guard interval naturally reduces the data capacity of the system. I.e. it becomes a balance between
5 cost and data capacity.

Upstream for WDM to TDM conversion the K-D-K configuration can also be simplified, in this case to a K-D configuration as exemplified in fig. 15. In contrast to the guard interval for the downstream D-K configuration there are no limitations for the upstream
10 K-D configuration and again K_1 can be omitted.

Symmetric few point to multi-point

The capacity of the point to multi-point architecture can be further increased by a so-called symmetric few point to multipoint architecture as exemplified in fig. 6. The main difference from the symmetric point to multipoint time-lens PON architecture disclosed
15 above is that a single wavelength TDM TX and RX in the OLT is replaced by the multi-wavelength TWDM TX array (301) and RX array (302) having a multiple M of wavelengths. However, the number M of wavelengths is typically much less than the ONU counts N. This few point to multipoint architecture can increase the total time-lens PON capacity by a factor M, by simply adding TDM TRX at different wavelengths in the
20 OLT. M wavelength TWDM TX array and RX array are exemplified in Fig. 7. At the ONU side, the individual ONU obtains increased bit rate at the original wavelength, without the requirement of a WDM TRX array.

Fig. 8 illustrates the M-wavelength TWDM (501) to N-wavelength WDM signal (502) (M
25 to N) conversion and vice versa (N to M conversion) through the time-lens signal processor (503). For M-TWDM to N-WDM conversion, the symbol rate of the TWDM signal is f_s , and the repetition frequency of the quadratic phase-modulation f_{PM} is set to f_s/N . The M-wavelength TWDM signal is converted to a N-wavelength WDM signal with channel spacing Δv_N , depending on the choice of K , which also determines the M-
30 TWDM channel spacing Δv_M . The symbol rate of the each converted WDM channel is multiplexed by M, which is Mf_s/N . The components and settings for both M-TWDM to N-WDM and N-WDM to M-TWDM can basically be the same.

Asymmetric point to multi-point and few point to multipoint

Some access networks require larger capacity for the downstream transmission than for the upstream transmission. In that case an asymmetric PON architecture in which the total upstream data rate is less than the downstream data rate can be suitable. An 5 example is illustrated in fig. 9. This embodiment combines the time-lens PON and traditional TDM PON, where the time-lens PON architecture is used for the high capacity demand of the downstream transmission, while the traditional TDM PON is used for the less demanding upstream transmission. The downstream part can be similar to the symmetric point to multipoint and few point to multipoint as described 10 above. The AWG (601) in the ODN has N+1 ports, where port 1 to N are used for downstream transmission, and the last port (N+1) is used only for upstream transmission. In the upstream part, the transmitter at each ONU (602, 603, 604) generates TDM channels at the same A_u that matches the transmission windows of the periodic AWG port no. N+1 at a different wavelength region according to $A_{uN+1} = A_{N+1} +$ 15 ΔA . At the remote node (RN) location, the upstream signals are separated by N WDM couplers (605), and combined to the AWG port no. N+1 by an N to 1 optical combiner (606). The TDM signal is transmitted back to the OLT through the same optical fiber at λ_{uN+1} . In the OLT, the upstream TDM signal is switched to the upstream RX using a WDM coupler (607).

20 *Advantages of time-lens PON*

Fig. 1 shows four examples a)-d) of prior art optical access systems where c) and d) show PON systems. Fig. 1(a) is point to point system that requires a large number of optical fibers and transmitters. Fig. 1(b) shows an active optical network that requires a large number of transmitters. Fig. 1(c) is an example of a TDM-PON system that is a 25 cost-efficient solution because only a single transmitter is required in the central office (CO). The TDM-PON principle is illustrated in further detail in fig. 2A. The WDM-PON system illustrated in fig. 1(d) is a point to point system with many technical advantages but this is not a cost-efficient solution. The WDM-PON principle is illustrated in further 30 detail in fig. 2B. Compared to these prior art solutions there are a number of advantages of time-lens PON:

Single (or few) transmitter(s) in central office (CO): Less cost and energy consumption, i.e. one of the advantages of existing TDM PON is maintained in time-lens PON.

Splitting loss is small and independent of the number of subscribers: In a conventional PON system, the use of passive optical splitter/combiner introduces a $\sim 10\log N$ [dB] splitting loss depending on the subscriber count N , which severely limits the user counts. In contrast to this, in the time-lens PON the optical splitter can be replaced, for example by a conventional passive AWG, with a much lower fixed loss (< 4 dB) regardless of the number of subscribers. This allows for efficient scale up of the amount of users.

No subscriber count N dependent SNR penalty: In a conventional PON system the OLT broadcasts the TDM signal to all ONUs. The actual signal power is therefore only $1/N$ of the total received power at each ONU. The larger integrated noise bandwidth also brings noise. This results in a SNR penalty proportional to $N^2 \sim N^3$. In contrast hereto each ONU only receives its own signal at the base bandwidth in time-lens PON. Hence, there is no subscriber count dependent SNR penalty in time-lens PON, resulting in much better receiver sensitivity, e.g. ~10 dB better than that of prior art TDM-PON with 32 users.

Better power budget: The reduced splitting loss and better receiver sensitivity result in a larger power budget of time-lens PON compared to prior art PON. The enhanced power budget is furthermore independent of the subscriber count. The enhanced power budget can be used to scale up the total capacity, user count and transmission reach efficiently.

No extra bandwidth requirement on the components at the ONU side: In a conventional PON system, the transceivers at the ONU side require a bandwidth which is tens of times of the actual used data rate. Upgrade of such a system requires a large amount of optoelectronic devices with even higher bandwidth for all ONUs - this is costly and results in higher energy consumption. In the presently disclosed time-lens PON, there is no extra bandwidth requirement, allowing re-use of the existing devices on the ONU side for tens of times more data capacity, which is more cost- and energy-efficient than the other prior art high capacity PON solutions.

No security issues: Prior art PON systems require data encryption, since each ONU has access to all the data sent to any of the other users on the PON. In the presently disclosed time-lens PON, a wavelength demultiplexer (e.g. an AWG) at the RN directs a different wavelength to each user. Thus, there are no security issues since users on

the time-lens PON do not have access to any of the other downstream wavelengths. Hence, security is guaranteed by the architecture of the physical network.

Dispersion tolerance: Conventional PON systems transmit high speed TDM signal in
5 the fiber link, which has poor dispersion tolerance - and the dispersion tolerance will become worse and worse when the speed of the TDM signal increases. The presently disclosed time-lens PON transmits low speed WDM signals in the fiber link, which has better dispersion tolerance than prior art PON systems.

10 **No Quality of Service (QoS) issues related to sharing the PON:** When bandwidth demand becomes high in prior art PON systems it can lead to QoS issues, e.g. how to fairly assign capacity to multiple high-demand users. This may lead to a requirement of larger buffer memories for users waiting to send data and issues regarding time delays and packet loss. In the presently disclosed time-lens PON, there is no issue regarding 15 QoS or privacy, since no optical signals are shared with anyone else connected to the time-lens PON. Even at the internet rush hour, the user experience is guaranteed.

The advantages listed above can be summarized as follows:

Feature	Prior art PON	Time-lens PON
TRX count in CO	1	1 (or few)
Splitting loss	$10\log N$ [dB]	< 5 dB
SNR Penalty	$N^2 \sim N^3$	Reference
Receiver sensitivity for 32 users	~ -10 dB	Reference
Security	No	Yes
Bandwidth at ONU	$N \times$ subscriber data rate	Subscriber data rate
Power budget	Small	Large
Dispersion tolerance	Bad	Good
QoS	Priority management	No issue

Example 1

20 The presently disclosed time-lens PON approach has been demonstrated experimentally. A 40-Gbit/s PON downstream transmission over 150-km 40-split unamplified SMF-plant has been obtained with a single-carrier OOK transmitter and low-cost 10-GHz APD-based receiver, achieving a power budget of 51.5 dB (35.5 dB/ch.) for a BER=3x10⁻⁶. Meanwhile, the same system achieves 128 Gb/s PON

over 100 km 64 split unamplified Fiber-Plant using optical TDM technique, showing flexibility and scalability of the presently disclosed scheme in terms of wavelength control and system capacity.

Principle and Experimental Setup

- 5 One example of the presently disclosed OLT structure / PON architecture is shown in Fig.3A and this setup is used here in example 1. In the optical line terminal (OLT), a single carrier TDM transmitter generates a high-speed TDM signal, which is then converted to a number of low-speed WDM channels using a time-lens based OFT signal processor, which comprises a dispersive medium with dispersion $D=\beta_2 L$,
- 10 followed by a quadratic phase modulation with chirp rate $K=1/D$. The converted WDM signal is transmitted through the wavelength splitter based outside plant, e.g. using an arrayed waveguide grating (AWG). At the ONU side, each ONU receives its own specific wavelength channel using low-speed components. Unlike transmitting a high speed TDM signal through a power splitter based outside plant, the proposed OLT
- 15 structure inherits advances from WDM-PON, e.g. higher dispersion tolerance, lower splitting loss, better receiver sensitivity, longer reach, security, and guaranteed quality of service but requires only one transmitter at the OLT and offers more flexibility and scalability.
- 20 The experimental setup is shown in Fig. 10. The output of an external cavity CW laser at 1581.5 nm is NRZ on-off keying (OOK) modulated in a Mach-Zehnder modulator (MZM). The data pattern used for modulation consists of 40x 1-Gb/s 2¹¹-1 PRBS TDM tributaries and 200-ps guard interval (GI) between every 40 TDM tributaries for OFT operation. A second MZM is used to carve the NRZ signal into a carrier-suppressed return-to-zero (CS-RZ) signal resulting in the 40 Gb/s CSRZ OOK signal with guard interval, as shown in Fig. 11(a), which can be directly converted to individual WDM channels using OFT without any further optical filtering. At the OFT, the obtained 40 Gb/s TDM signal is firstly dispersed in 470 m dispersion compensation fiber (DCF).
- 25 The quadratic phase modulation is implemented based on a four-wave mixing (FWM) process in a highly nonlinear fibre (HNLF) using linearly chirped rectangular pump pulses. The source of pump pulses is a 10-GHz mode-locked laser (MLL) at 1542 nm, which are spectrally broadened in 400 m HNLF. A MZM is used to decrease the repetition rate of the MLL to 1-GHz, to enable the OFT operating at 1 GHz. The OFT pump is obtained by filtering the broadened spectrum in a wavelength selective switch (WSS3) and propagation in 1.1 km dispersion compensation fiber (DCF). The chirp rate
- 30
- 35

K = 0.014 ps⁻² is set for conversion of 20 ps temporal spacing to 46 GHz frequency grid. The resulting spectrum is shown in Fig. 11(b). The generated idler is the 40-channel WDM signal converted from the 40-Gb/s TDM signal. After extraction with an optical bandpass filter, the power levels of the generated WDM channels are equalized 5 in WSS1 . The spectrum of the 40-channel WDM signal after power equalization is shown in Fig. 11(c), where 40 1-Gb/s WDM channels with 46 GHz spacing are observed. The WDM signal obtained is optically boosted to 21.5 dBm (5.5 dBm/ch.) using an erbium doped fibre amplifier (EDFA), and launched into a 150 km unamplified SMF fibre link. The wavelength splitter is implemented by another WSS. In the ONU, 10 each spitted WDM channel is directly received by a low-cost 10-GHz APD/TIA based receiver.

Experimental results

Fig. 12(a) shows the back-to-back (B2B) BER performance of some selected 1-Gb/s RZ-OOK WDM channels after TDM to WDM conversion. For reference, a 10-Gb/s 15 NRZ-OOK baseline BER curve using the same APD is also shown. 11 dB better receiver sensitivity is gained at BER=10⁻⁹ from the APD based receiver, when receiving lower symbol rate RZ signals. The BER performance of all 40 WDM channels before transmission at a fixed received power of -35 dBm is shown in Fig. 4(b), and the BER 20 after 150 km transmission without re-amplification or dispersion compensation at -30 dBm is shown in Fig. 12(c). After 150 km transmission, all converted WDM channels achieve BER< 3x1 0⁻⁶, i.e. well below the forward error-correcting (FEC) threshold of BER=1 0⁻³, indicating a BER of 10⁻¹² can be achieved for all WDM channels after error correction. The BER fluctuations between WDM channels which can be observed both before and after the transmission, are due to the inter-channel-interference (ICI) 25 introduced at the OFT, from the intersymbol interference of the TDM signal. The BER of the edge channels are better due to less ICI. The power penalty after 150 km transmission is ~7 dB. This is due to the fibre nonlinearity and the dispersion during the transmission, which can be observed from the waveform of a WDM channel before , cf. Fig. 12(d), and after the transmission, cf. Fig. 12(e). The power budget is 5 1.5 dB 30 (35.5 dB/ch) for a BER=3x1 0⁻⁶ after 150 km transmission.

Flexibility and scalability

The proposed OLT structure / PON architecture is highly flexible in terms of wavelength allocation, as the OFT allows tuning of the signal wavelength in sub nanoseconds by encoding (remapping) the TDM signal in time-domain, without tuning the actual

wavelength of the optical source. As shown in Fig. 13, with OFT and the TDM signal encoding, a 20-channel WDM signal with 92 GHz spacing can be realized by turning off every second TDM tributaries (Fig. 13(a)). Fig. 13(b) shows the wavelength allocation of a 10-channel WDM signal using OFT, which can reduce the complexity for 5 wavelength alignments of the WDM channels to the AWG ports. Fig. 13(c) shows a designed OFT output, which is obtained by encoding the TDM signal as shown in Fig. 13(d), indicating that the proposed scheme is highly flexible in terms of WDM channel count, channel spacing and their wavelength allocation. Furthermore, the same system is also used to achieve 128 Gb/s PON over 100 km 64 split unamplified fibre-plant 10 using optical TDM technique. The setup of the OTDM transmitter is shown in Fig. 10, where the output of the MLL is OOK data modulated to 8 Gb/s and then OTDM to 128 Gb/s using a fibre delay line based OTDM multiplexer. The spectrum of the OFT converted 64x2 Gb/s WDM signal with 37 GHz frequency grid and all channel BER performance after 100 km are shown in Fig. 13(e), where all converted WDM channels 15 achieve a BER<5x1 0⁻⁶ showing the flexibility and scalability of the presently disclosed principle.

Hence, a highly flexible and scalable OLT structure for WDM-PON using OFT has been 20 verified experimentally. A long-reach 40-Gb/s PON transmission over 150-km 40-split unamplified fibre-plant was successfully demonstrated with a single OOK transmitter and low-cost 10-GHz APD-based receiver.

Example 2

In this example the scalability of the presently disclosed solution is investigated and 25 128x2 Gb/s WDM PON downstream transmission over a 100-km unamplified SMF- plant is demonstrated using a 200 m highly nonlinear fiber (HNLF, for example from OFS). Although all 128 generated WDM channels achieve BERs below the 10⁻³ forward error-correction (FEC) limit after transmission, a bandwidth limitation of the HNLF is observed, which will limit the scalability of the proposed scheme. To overcome 30 this issue the use of AlGaAs-on-insulator (AlGaAsOI) nonlinear waveguides [6,7] for implementing the time lens is investigated. The same 128x2 Gb/s WDM PON system using an AlGaAs device is demonstrated, which achieves similar performance as HNLF, but without showing indications of having reached a bandwidth limitation.

Principle and Experimental Setup

The principle is the same as shown in Fig. 3a. In the OLT, a single TDM transmitter generates a high-speed TDM signal, which is then converted to a number of lower-speed WDM channels using a time-lens based OFT signal processor, composed of a dispersive medium followed by a quadratic phase modulator. The generated WDM signals are transmitted through a wavelength-splitting *outside plant* using e.g. an arrayed waveguide grating (AWG). Then, each ONU receives its own specific wavelength channel using low-speed components. To demonstrate the scalability, we constructed a TDM transmitter capable of providing very high TDM rates, although a standard commercial e/o-TDM transmitter can be used for more practical systems addressing 40-60 Gb/s total rates.

The experimental setup is shown in Fig. 16. The output of a 10 GHz supercontinuum (SC) source is on-off keying modulated (MZM1) with 4x2-Gb/s 2^{15} -1 PRBS TDM tributaries. The output is further optical time-division multiplexed (OTDM) to 128x2-Gb/s using a fiber based OTDM multiplexer. A 100-ps guard interval is added between every 128 TDM tributaries for OFT operation. A wavelength selective switch (WSS1) carves the signal into a 1.2 ps Gaussian shape with a 38% duty cycle. This signal is directly converted to individual WDM channels using OFT, based on four-wave mixing (FWM) in a highly nonlinear device using linearly chirped rectangular pump pulses. The AlGaAs nanowire is a dispersion engineered straight 4 mm long AlGaAsOI waveguide, which includes tapering sections for low loss interfacing with tapered optical fibers. The main waveguide section is ~3 mm long and the total insertion loss is 6 dB. The HNLF has a length of 200 m, non-linear coefficient $\gamma \sim 10 \text{ W}^{-1}\text{km}^{-1}$, zero-dispersion wavelength -1560 nm and dispersion slope 0.005 ps/(nm²-km) [8]. The pump pulses are generated from the same SC source followed by MZM2, which is used to decrease the repetition rate to 2 GHz for OFT operation. The OFT pump is obtained by filtering in WSS2 followed by 300 m DCF propagation to map the 3.125-ps TDM tributary spacing on a 25-GHz frequency grid. The optimized input power to the AlGaAs waveguide is 22.0 dBm for the pump and 13.4 dBm for the OTDM signal, and the optimized input power to the HNLF is 19.5 dBm and 11 dBm, respectively. After OFT, the generated 128x2-Gb/s WDM channels are boosted to 21 dBm using an EDFA, and launched into a 100 km unamplified SMF fiber link. After transmission, a tunable bandpass filter (BPF) is used to select the individual WDM channels, one at a time, to be directly detected by an APD/TIA receiver.

The experimental results are shown in Figs. 17A-C. The output spectra with HNLF and AlGaAs device are shown in Fig. 17A with the AlGaAs device spectrum on top and the HNLF in the bottom.

5 *HNLF*

The FWM idler consists of 128 WDM channels at 2 Gb/s each. A zoom-in on the idler is shown in Fig. 17B, in which the Fourier transformation of the 256 Gb/s Gaussian OTDM signal to 128 individual WDM channels with 25 GHz spacing, can be observed. However, the power difference between the short and long wavelength channels is 10 more than 15 dB as shown in Figs. 17A and 17B. This is due to the limited nonlinear operational bandwidth of the HNLF, requiring additional equalization before transmission. With power equalization using a wavelength selective switch, all 128 WDM channels after 100 km transmission achieve BERs below the FEC limit at BER = 10^{-3} , as shown in Fig. 17C.

15 *AlGaAs device*

The power difference between the individual channels is less than 3 dB as shown in Fig. 17B. After 100 km transmission, all 128 WDM channels achieve BERs $< 10^{-3}$, as shown in Fig. 17C. The average BER values before (solid line) and after transmission (dashed line) with the AlGaAs waveguide are similar to that with the HNLF. For both 20 HNLF and AlGaAs, BER $< 10^{-3}$ is obtained for all 128 WDM channels after transmission, although it is difficult for HNLF to scale to higher channel counts, due to the limited operational bandwidth. In contrast, the AlGaAs waveguide shows a greater potential for further scaling of the channel count.

Conclusion

25 A 128x2-Gb/s WDM-PON system with 100 km unamplified transmission based on a single TDM time lens source is demonstrated with both an AlGaAs waveguide and a HNLF. All 128 converted WDM channels achieve BERs below the 10^{-3} FEC threshold after transmission in both cases, which confirms the high scalability of the proposed scheme. The experimental results show that the AlGaAs waveguide has potential for 30 further scaling of the subscriber count and of the total capacity of the proposed OLT structure.

Items

- 15 Further details of the present disclosure are provided in the following items.
1. An optical line terminal for a passive optical network, comprising
 - at least one transmitter for generating a time division multiplexed (TDM) downstream optical data signal,
 - a first time lens optical signal processor configured to convert the downstream TDM signal to a downstream WDM signal for distribution to a plurality of users, and
 - at least one receiver for receiving and processing an upstream signal from said users.

20

 2. The optical line terminal according to item 1, further comprising a second time lens optical signal processor configured to convert an upstream WDM signal received from said users to an upstream TDM signal, and at least one TDM receiver for demultiplexing and processing the upstream TDM signal.

25

 3. The optical line terminal according to any of the preceding items, further comprising at least one WDM receiver for demultiplexing an upstream WDM signal received from said users.

4. The optical line terminal according to any of the preceding items, further comprising at least one WDM coupler for separating an upstream signal from said users from the downstream WDM signal.
5. The optical line terminal according to any of the preceding items, further comprising at least one optical amplifier for amplifying the downstream WDM signal and/or the upstream WDM signal.
6. The optical line terminal according to any of the preceding items, wherein the first time lens optical signal processor comprises a dispersive medium with dispersion $D=\beta_2 L$ followed by a phase modulation element, preferably a quadratic phase modulation element, with chirp rate $K=1/D$.
7. The optical line terminal according to any of the preceding items 6, wherein a predefined minimum amount of guard interval is provided in the time domain of the downstream TDM signal.
8. The optical line terminal according to any of the preceding items 7, wherein the predefined minimum amount of guard interval is related to the signal bandwidth $\Delta\lambda$, the dispersion D , and the gap between the PM windows T_g according to
$$GI \geq \frac{2\pi c}{\lambda^2} DA\lambda + T_g$$
where c is the speed of the light and A is the signal wavelength.
9. The optical line terminal according to any of the preceding items, wherein the second time lens optical signal processor comprises a phase modulation element, preferably a quadratic phase modulation element, with chirp rate $K=1/D$ followed by a dispersive medium with dispersion $D=\beta_2 L$.
10. The optical line terminal according to any of the preceding items, wherein the first and/or the second time lens optical signal processor comprises two phase modulation stages, preferably quadratic phase modulation stages, separated by a dispersive medium in a K-D-K configuration.

11. The optical line terminal according to any of the preceding items 10, wherein $\delta\phi = K_1 \ell / 2$ in the first phase modulation stage with linear chirp rate K_1 , $\delta\phi = K_2 f / 2$ in second phase modulation stage with linear chirp rate K_2 , and wherein $D = \beta_2 L$ in the dispersion medium where β_2 is the 2nd order dispersion and L is the length, such that $K_1 K_2 = 1/D$.
- 5
12. The optical line terminal according to any of the preceding items 10-1 1, wherein the chirp rate Δt determines the scaling factor between the time and frequency domains according to $\Delta t = 2\pi A_i / K$.
- 10
13. The optical line terminal according to any of the preceding items 6-1 2, wherein the dispersive medium is a length of optical fiber, such as transmission fiber, such as a standard single mode fiber (SSMF), such as a dispersion compensating fibre (DCF).
- 15
14. The optical line terminal according to any of the preceding items 6-1 3, wherein the phase modulation stage(s) comprise(s) a length of highly non-linear fiber.
- 20
15. The optical line terminal according to any of the preceding items 6-14, wherein the phase modulation stage(s) comprise(s) at least one AlGaAs-on-insulator waveguide.
- 25
16. The optical line terminal according to any of the preceding items 6-1 5, wherein the phase modulation is based on four-wave mixing (FWM), e.g. using chirped pump pulses, cross-phase modulation (XPM) e.g. using parabolic intensity profile pump pulses, or electro-optic phase-modulation e.g. using an electrical driving signal.
- 30
17. The optical line terminal according to any of the preceding items, further comprising a clock recovery unit configured to synchronize the second time-lens signal processor to the upstream WDM signal.
- 35
18. The optical line terminal according to any of the preceding items, wherein the single channels of the upstream WDM signal are symbol-wise synchronized at the input of the second time-lens optical signal processor.

19. The optical line terminal according to any of the preceding items, further comprising at least one control unit connected to the transmitter and/or the receiver and configured to control the wavelength and timing of the signals.
- 5 20. The optical line terminal according to any of the preceding items, wherein the transmitter comprises a multi-wavelength time and wavelength division multiplexed (TWDM) array configured to generate a time division multiplexed downstream optical signal at M different wavelengths, and where M is less than the number N of signal wavelengths in the downstream WDM signal.
- 10 21. The optical line terminal according to any of the preceding items 20, wherein the receiver comprises a multi-wavelength time and wavelength division multiplexed (TWDM) array configured to receive and process a time division multiplexed upstream optical signal at M different wavelengths.
- 15 22. The optical line terminal according to any of the preceding items, wherein the receiver is configured to receive and process a time division multiplexed upstream optical signal at a single wavelength.
- 20 23. A passive optical network (PON) system comprising the optical line terminal according to any of the preceding items.
24. The PON system according to item 23, further comprising
- 25 - an optical fiber infrastructure for distributing the downstream and upstream signals,
- at least one remote node for splitting the downstream WDM signal into separate wavelength signals.
- 30 25. The PON system according to any of preceding items 23-24, wherein the at least one remote node is configured for combining upstream separate wavelength signals into an upstream WDM signal.
- 35 26. The PON system according to any of preceding items 23-25, further comprising separate ONU transmitters located at each user configured to generate separate wavelength upstream signals that can be combined to a single (or

few) upstream WDM signals.

27. The PON system according to any of preceding items 23-26, further comprising separate ONU transmitters located at each user configured to generate upstream signals at one predefined wavelength that can be combined to a single (or few) upstream TDM signals.
5
28. The PON system according to any of preceding items 23-27, wherein the each network line between the remote node(s) and the separate ONUs comprises a splitter for separating the upstream signal at said predefined wavelength from the downstream separate wavelength signals.
10
29. The PON system according to any of preceding items 23-28, wherein the remote node comprises at least one arrayed waveguide grating (AWG) for splitting the downstream WDM signal into separate wavelength signals and/or for combining the upstream signals into a single WDM or TDM upstream signal.
15
30. A method for generating a downstream WDM optical signal for use in a passive optical network system, comprising the steps of
20
 - generating a time division multiplexed (TDM) signal, and
 - converting the TDM signal to a downstream wavelength division multiplexed (WDM) signal for distribution to a plurality of users in a passive optical network by means of a first time lens optical signal processor.
- 25 31. A method for receiving an upstream WDM optical signal distributed from a plurality of users in a passive optical network system, comprising the steps of
 - converting the upstream WDM signal to a time division multiplexed (TDM) optical signal by means of a second time lens optical signal processor, and
 - demultiplexing and processing the TDM signal to individual signals.
30
32. The method according to any of items 30-31 employing any of the features employed in items 1-29.

Claims

1. An optical line terminal for a passive optical network, comprising
 - at least one transmitter for generating a time division multiplexed (TDM) downstream optical data signal,
 - a first time lens optical signal processor configured to convert the downstream TDM signal to a downstream wavelength division multiplexed (WDM) signal for distribution to a plurality of users, and
 - at least one receiver for receiving and processing an upstream signal from said users.

10

2. The optical line terminal according to claim 1, further comprising a second time lens optical signal processor configured to convert an upstream WDM signal received from said users to an upstream TDM signal, and at least one TDM receiver for demultiplexing and processing the upstream TDM signal.

15

3. The optical line terminal according to any of the preceding claims, wherein the first time lens optical signal processor comprises a dispersive medium with dispersion $D = \frac{c}{\lambda} L$ followed by a phase modulation element, preferably a quadratic phase modulation element, with chirp rate $K = 1/D$, and wherein the second time lens optical signal processor comprises a phase modulation element, preferably a quadratic phase modulation element, with chirp rate $K = 1/D$ followed by a dispersive medium with dispersion $D = \frac{c}{\lambda} L$.

20

4. The optical line terminal according to claim 3, wherein a predefined minimum amount of guard interval is provided in the time domain of the downstream TDM signal, the predefined minimum amount of guard interval is related to the signal bandwidth $\Delta\lambda$, the dispersion D , and the gap between the phase modulation (PM) windows T_g according to

$$GI \geq \frac{2\pi c}{\lambda^2} DA\lambda + T_g$$

25

where c is the speed of the light and A is the signal wavelength.

5. The optical line terminal according to any of the preceding claims, wherein the first and/or the second time lens optical signal processor comprises two phase modulation stages, preferably quadratic phase modulation stages, separated by

a dispersive medium in a K-D-K configuration.

6. The optical line terminal according to any claim 4, wherein $\delta\phi = K_1 t^2/2$ in the first phase modulation stage with linear chirp rate K_1 , $\delta\phi = K_2 f/2$ in second phase modulation stage with linear chirp rate K_2 , and wherein $D = \beta_2 L$ in the dispersion medium where β_2 is the 2nd order dispersion and L is the length, such that $K_1 = K_2 = 1/D$, and wherein the chirp rate K determines the scaling factor between the time and frequency domains according to $At = 2\pi A_i/K$.
- 10 7. The optical line terminal according to any of the preceding claims, wherein the transmitter comprises a multi-wavelength time and wavelength division multiplexed array configured to generate a time division multiplexed downstream optical signal at M different wavelengths, and where M is less than the number N of signal wavelengths in the downstream WDM signal.
- 15 8. The optical line terminal according to claim 7, wherein the receiver comprises a multi-wavelength time and wavelength division multiplexed array configured to receive and process a time division multiplexed upstream optical signal at M different wavelengths.
- 20 9. The optical line terminal according to any of the preceding claims, wherein the receiver is configured to receive and process a time division multiplexed upstream optical signal at a single predefined wavelength.
- 25 10. A passive optical network (PON) system comprising the optical line terminal according to any of the preceding claims.
11. The PON system according to claim 10, further comprising
 - an optical fiber infrastructure for distributing the downstream and upstream signals,
 - at least one remote node for splitting the downstream WDM signal into separate wavelength signals.
- 30 12. The PON system according to any of preceding claims 10-11, wherein the at least one remote node is configured for combining upstream separate
- 35

wavelength signals into an upstream WDM signal.

- 5 13. The PON system according to any of preceding claims 10-12, further comprising separate ONU transmitters located at each user and configured to generate separate wavelength upstream signals that can be combined to a one or more upstream WDM signals.
- 10 14. The PON system according to any of preceding claims 10-13, further comprising separate ONU transmitters located at each user and configured to generate upstream signals at one predefined wavelength that can be combined to one or more upstream TDM signals.
- 15 15. The PON system according to any of preceding claims 10-14, wherein each network line between the remote node(s) and the separate ONUs comprises an optical splitter for separating the upstream signal at said predefined wavelength from the downstream separate wavelength signals.
- 20 16. A method for generating a downstream WDM optical signal for use in a passive optical network system, comprising the steps of
 - generating a time division multiplexed (TDM) signal, and
 - converting the TDM signal to a downstream wavelength division multiplexed (WDM) signal for distribution to a plurality of users in a passive optical network by means of a first time lens optical signal processor.
- 25 17. A method for receiving an upstream WDM optical signal distributed from a plurality of users in a passive optical network system, comprising the steps of
 - converting the upstream WDM signal to a time division multiplexed (TDM) optical signal by means of a second time lens optical signal processor, and
 - demultiplexing and processing the TDM signal to individual signals.

INTERNATIONAL SEARCH REPORT

International application No
PCT/EP2018/073867

A. CLASSIFICATION OF SUBJECT MATTER
INV. H04J14/02

ADD.

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)
H04J

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

EPO-Internal , WPI Data

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A	EP 3 107 306 A1 (ZTE CORP [CN]) 21 December 2016 (2016-12-21) paragraph [0002] ; figure 1 ----- -/- -	1-17

Further documents are listed in the continuation of Box C.

See patent family annex.

* Special categories of cited documents :

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier application or patent but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

"&" document member of the same patent family

Date of the actual completion of the international search
