ABSTRACT

The e^T program is an open source electronic structure package with emphasis on coupled cluster and multilevel methods. It includes efficient spin adapted implementations of ground and excited singlet states, as well as equation of motion oscillator strengths, for CCS, CC2, CCSD, and CC3. Furthermore, e^T provides unique capabilities such as multilevel Hartree–Fock and multilevel CC2, real-time propagation for CCS and CCSD, and efficient CC3 oscillator strengths. With a coupled cluster code based on an efficient Cholesky decomposition algorithm for the electronic repulsion integrals, e^T has similar advantages as codes using density fitting, but with strict error control. Here, we present the main features of the program and demonstrate its performance through example calculations. Because of its availability, performance, and unique capabilities, we expect e^T to become a valuable resource to the electronic structure community.

I. INTRODUCTION

During the last five decades, a wide variety of models and algorithms have been developed within the field of electronic structure theory and many program packages are now available to the community.¹ Programs with extensive coupled cluster functionality include CFOUR,² Dalton,³ GAMESS,⁴ Gaussian,⁵ Molcas,⁶ Molpro,⁷ NWChem,⁸ ORCA,⁹ PSI4,¹⁰ QChem,¹¹ and TURBOMOLE.¹² Although these are all general purpose quantum chemistry programs, each code is particularly feature rich or efficient in specific areas. For instance, a large variety of response properties¹³ have been implemented in Dalton, CFOUR is particularly suited for gradients^{14,15} and geometry optimization, and QChem is leading in equation of motion^{16,17} (EOM) features. However, due to the long

history of many of these programs, it can be challenging to modify and optimize the existing features or to integrate new methods and algorithms.

In 2016, we began developing a coupled cluster code based on Cholesky decomposed electron repulsion integrals.^{18,19} While starting anew, we have drawn inspiration from Dalton³ and used it extensively for testing purposes. Our goal is to create an efficient, flexible, and easily extendable foundation upon which coupled cluster methods and features—both established and new—can be developed. That code has now evolved beyond a coupled cluster code into a freestanding electronic structure program. It is named e^T after the expression for the coupled cluster ground state wave function,²⁰

$$|\Psi\rangle = e^T|R\rangle, \quad (1)$$

and released as an open source program licensed under the GNU General Public License 3 (GPL 3.0).

The first version of e^T offers an optimized Hartree–Fock (HF) code and a wide range of standard coupled cluster methods. It includes the most efficient published implementations of Cholesky decomposition of the electron repulsion integrals²¹ and of coupled cluster singles, doubles, and perturbative triples^{22,23} (CC3). Furthermore, e^T features the first released implementations of multilevel HF²⁴ (MLHF), multilevel coupled cluster singles and perturbative doubles^{25,26} (MLCC2), and explicitly time-dependent coupled cluster singles (TD-CCS), and singles and doubles (TD-CCSD) theory. All coupled cluster models can be used in quantum mechanics/molecular mechanics^{27,28} (QM/MM) calculations or be combined with the polarizable continuum model^{29,30} (PCM).

e^T is primarily written in modern Fortran using the Fortran 2008 standard. The current version of the code is interfaced to two external libraries: Libint 2³¹ for the atomic orbital integrals and PCMSolver 1.2³² for PCM embedding. In addition, e^T applies the runtest library³³ for testing and a CMake module from autotcmake³⁴ to locate and configure BLAS and LAPACK.

With the introduction of the 2003 and 2008 standards, Fortran has become an object oriented programming language. We have exploited this to make e^T modular, readable, and easy to extend. Throughout the program, we use OpenMP³⁵ to parallelize computationally intensive loops and BLAS and LAPACK routines whenever possible. In order to preserve code quality, extensive code review and enforcement of a consistent standard have been prioritized from the outset. While this requires extra effort from both developers and maintainers, it pays dividends in code readability and flexibility.

II. PROGRAM FEATURES

A. Coupled cluster methods

The e^T program features all standard coupled cluster methods up to perturbative triples: singles (CCS), singles with perturbative doubles³⁶ (CC2), singles and doubles³⁷ (CCSD), singles and doubles with non-iterative perturbative triples³⁸ [CCSD(T)], and singles and doubles with perturbative triples²² (CC3). At the CCSD(T) level of theory, only ground state energies can be computed. For all other methods, efficient spin adapted implementations of ground and excited singlet states are available. Moreover, dipole and quadrupole moments, as well as EOM oscillator strengths, can be calculated. Equation of motion polarizabilities are available at the CCS, CC2, and CCSD levels of theory.

A number of algorithms are implemented to solve the coupled cluster equations. For linear and eigenvalue equations, we have implemented the Davidson method.³⁹ This algorithm is used to solve the ground state multiplier equations, response equations, and excited state equations. To handle nonlinear coupled cluster equations, we have implemented algorithms that use direct inversion of the iterative subspace^{40,41} (DIIS) to accelerate convergence. The ground state amplitude equations can be solved using DIIS combined with the standard^{1,42} quasi-Newton algorithm or exact Newton–Raphson. We also use a DIIS-accelerated algorithm⁴³ for

the nonlinear excited state equations in CC2 and CC3. Our implementation of DIIS incorporates the option to use the related conjugate residual with optimal trial vectors^{44,45} (CROP) method for acceleration. For the nonperturbative coupled cluster methods, the asymmetric Lanczos algorithm is also available.^{46,47}

The time-dependent coupled cluster equations can be explicitly solved for CCS and CCSD^{48,49} using Euler, Runge–Kutta 4 (RK4), or Gauss–Legendre (GL2, GL4, and GL6) integrators. This requires implementations of the amplitude and multiplier equations with complex variables. Any number of classical electromagnetic pulses can be specified in the length gauge, assuming that the dipole approximation is valid. A modified version of the fast Fourier transform library FFTPACK 5.1⁵⁰ is used to extract frequency domain information.

B. Cholesky decomposition for the electronic repulsion integrals

Cholesky decomposition is an efficient method to obtain a compact factorization of the rank deficient electron repulsion integral matrix.^{18,19,51} All post-HF methods in e^T rely on the Cholesky vectors to construct the electron repulsion integrals. One advantage of factorization is the reduced storage requirements; the size of the Cholesky vectors scales as $\mathcal{O}(n_{\text{AO}}^3)$, while the full integral matrix scales as $\mathcal{O}(n_{\text{AO}}^4)$. The Cholesky vectors are kept in memory when possible but are otherwise stored on disk. Another advantage is that they allow for an efficient construction and transformation of subsets of the integrals. The Cholesky decomposition in e^T is highly efficient, consisting of a two-step procedure that reduces both storage requirements and computational cost compared to earlier algorithms. For a description of the algorithm and performance comparisons to Molcas,⁶ see Ref. 21.

C. Hartree–Fock

The restricted HF (RHF) and unrestricted HF (UHF) models are implemented in e^T . The implementations are integral direct and exploit Coulomb and exchange screening and permutation symmetry. We use a superposition of atomic densities⁵² (SAD) initial guess constructed from spherically averaged UHF calculations on the constituent atoms. The Hartree–Fock equations are solved using a Roothan–Hall self-consistent field (SCF) algorithm accelerated by either DIIS or CROP. To improve the screening and reduce the number of integrals that must be evaluated, density differences are used to construct the Fock matrix.

D. Multilevel and multiscale methods

In MLHF, a region of the molecular system is defined as active. A set of active occupied orbitals are obtained through a restricted, partial Cholesky decomposition of an initial idempotent AO density matrix.⁵³ The active virtual orbitals are obtained by constructing projected atomic orbitals^{54,55} (PAOs) centered on the active atoms. The PAOs are orthonormalized through the canonical orthonormalization procedure.⁵⁶ The MLHF equations are solved using a DIIS accelerated, MO based, Roothan–Hall SCF algorithm. Only the active MOs are optimized.⁵⁷

The most expensive step of an MLHF calculation is the construction of the inactive two-electron contribution to the Fock

matrix. As the inactive orbitals are frozen, it is only necessary to calculate this term once. The iterative cost in MLHF is dominated by the construction of the active two-electron contribution to the Fock matrix. An additional Coulomb and exchange screening, which targets accuracy of the matrix in the active MO basis, reduces the cost. The active orbitals are localized, and consequently, the elements of the AO Fock matrix that correspond to AOs distant from the active atoms will not significantly contribute to the active MO Fock matrix. This is similar to the screening used in MLHF specific Cholesky decomposition of the electron repulsion integrals.²¹

In MLCC2,^{23,25,26,58} an active orbital space is treated at the CC2 level of theory, while the remaining inactive orbitals are treated at the CCS level of theory. MLCC2 excitation energies are implemented in e^T . The active space is constructed using the approximated correlated natural transition orbitals,^{59,60} Cholesky orbitals, or Cholesky occupied orbitals and PAOs spanning the virtual space.

Frozen orbitals are implemented for all coupled cluster methods in e^T . In addition to the standard frozen core (FC) approximation, reduced space coupled cluster calculations can be performed using semi-localized orbitals. This type of calculation is suited to describe localized properties. In reduced space calculations, the occupied space is constructed from Cholesky orbitals, and PAOs are used to generate the virtual space.

Two QM/MM approaches are available in e^T : electrostatic QM/MM embedding⁶¹ and the polarizable QM/Fluctuating Charge⁶² (QM/FQ) model. In the former, the QM density interacts with a set of fixed charges placed in the MM part of the system.⁶¹ In QM/FQ, the QM and MM parts mutually polarize. Each atom in the MM part has a charge that varies as a response to differences in atomic electronegativities and the QM potential.⁶² These charges enter the QM Hamiltonian through a term that is nonlinear in the QM density.⁶³

PCM embedding can be used in e^T for an implicit description of the external environment. A solute is described at the QM level and is placed in a molecule shaped cavity. The environment is described in terms of an infinite, homogeneous, continuum dielectric that mutually polarizes with the QM part, as in QM/FQ.⁶⁴

In the QM/PCM and QM/FQ implementations, additional terms are only added to the Fock matrix. Additional terms at the coupled cluster level can also be considered.^{65–69}

E. Spectroscopic properties and response methods

Coupled cluster is one of the most accurate methods for modeling spectroscopic properties, and both ultraviolet-visible (UV/vis) and x-ray absorption spectra can be modeled in e^T . Core excitations are obtained through the core valence separation (CVS) approximation.⁷⁰ CVS is implemented as a projection^{71,72} for CCS, CC2, MLCC2, and CCSD. For CC3, amplitudes and excitation vector elements that do not contribute are not calculated. This reduces the scaling of the iterative computational cost for excited states from $\mathcal{O}(n_{\text{MO}}^7)$ to $\mathcal{O}(n_{\text{MO}}^6)$.

Intensities are obtained from EOM oscillator strengths,^{16,17} which are available for CCS, CC2, CCSD, and CC3. In addition, linear response⁴⁸ (LR) oscillator strengths can be calculated at the CCS level of theory. The asymmetric Lanczos algorithm^{46,47} can be used to directly obtain both energies and EOM oscillator strengths

for CCS, CC2, and CCSD. It can also be combined with the CVS approximation.

Real-time propagation offers a nonperturbative approach to model absorption spectra. Following an initial pulse that excites the system, the dipole moment from the subsequent time evolution can be Fourier transformed to extract the excitation energies and intensities.

Valence ionization potentials are implemented for CCS, CC2, and CCSD. A bath orbital that does not interact with the system is added to the calculation. Excitation vector components not involving this orbital are projected out in an approach similar to the projection in CVS.^{71,72}

III. ILLUSTRATIVE APPLICATIONS AND PERFORMANCE TESTS

In this section, we will demonstrate some of the capabilities of e^T with example calculations. Energy thresholds refer to the change in energy from the previous iteration. The maximum norm of the gradient vector is used in Hartree–Fock calculations. For coupled cluster calculations in e^T and Dalton, residual thresholds refer to the L^2 norm of the residual vectors. Finally, the Cholesky decomposition threshold refers to the largest absolute error on the diagonal of the electron repulsion integral matrix. This threshold gives an upper bound to the error of all matrix elements. Coupled cluster calculations were performed with either Cholesky vectors or electron repulsion integrals in memory. All geometries are available from Ref. 73.

A. Coupled cluster methods

The CC2 method is known to yield excitation energies with errors of about 0.1–0.4 eV for valence states with single excitation character.^{74–76} The iterative cost of CC2 scales as $\mathcal{O}(n_{\text{MO}}^5)$, and it may be implemented with an $\mathcal{O}(n_{\text{MO}}^2)$ memory requirement. In Table I, we report the lowest FC-CC2/aug-cc-pVDZ excitation energy of the antibiotic rifampicin⁷⁷ (chemical formula $\text{C}_{43}\text{H}_{58}\text{N}_4\text{O}_{12}$, see Fig. 1). The calculated excitation energy is 2.58 eV, which is consistent with the orange color of the compound. The ground state was converged to a residual threshold of 10^{-6} , and the excited state was converged to residual and energy thresholds of 10^{-3} and 10^{-6} , respectively. We used a Cholesky decomposition threshold of 10^{-2} , which is sufficient to ensure accuracy of excitation energies in CC2 and CCSD (see Table IV). The calculation was performed on two Intel Xeon Gold 6138 processors using 40 threads and 360 GB shared memory. The average iteration time for the ground state equations was 73 min, and the average iteration time for the excited state equations was 9 h.

TABLE I. The lowest FC-CC2/aug-cc-pVDZ excitation energy (ω) of rifampicin. n_{frozen} is the number of frozen core orbitals.

n_{AO}	n_{MO}	n_{frozen}	ω
1879	1865	59	2.579 eV

FIG. 1. Rifampicin.

At the CCSD level of theory, we report calculations for the amino acid tryptophan⁷⁸ (chemical formula $C_{11}H_{12}N_2O_2$) and excitation energies for the psychoactive agent lysergic acid diethylamide (LSD)⁷⁹ (chemical formula $C_{20}H_{25}N_3O$). Tryptophan and LSD are depicted in Fig. 2.

For tryptophan, we have determined the four lowest excitation energies and the corresponding oscillator strengths at the CCSD/aug-cc-pVDZ level of theory ($n_{MO} = 453$). Energies and oscillator strengths are reported in Table II. Timings for e^T 1.0, Dalton 2018, and QChem 5.0 are given in Table III. Thresholds in e^T were set to target an energy convergence of 10^{-6} : the residuals were converged to 10^{-6} for the ground state and 10^{-3} for the excited states (assuming quadratic errors for the energy). In QChem, thresholds for ground and excited states were set to 10^{-6} . We report the total wall time for each calculation. The excited state timing includes the time to converge ground state and excited state equations. The oscillator strength timing also includes the time to solve the multiplier and the left excited state equations. e^T and QChem are equally efficient for the CCSD ground state, while Dalton is considerably slower. For the CCSD excited state calculation, QChem reduced the wall time by a factor of 1.6 compared to e^T and a factor of 5.6 compared to Dalton. For the oscillator strength calculations, QChem reduced the wall time by a factor of 2.7 compared to e^T . The superior performance of QChem for oscillator strengths is primarily due to an efficient starting guess for the left excitation vectors, which are restarted from the right vectors: only 27 transformations are needed to converge all four roots. In e^T 1.0, orbital differences are used as the starting guess for both left and right states, which explains the poorer performance for oscillator strengths.

FIG. 2. Tryptophan (left) and LSD (right).

TABLE II. CCSD/aug-cc-pVDZ excitation energies (ω) and oscillator strengths (f_ω) for tryptophan.

	ω (eV)	f_ω

S_2	4.821	0.001
S_3	4.972	0.088
S_4	5.364	0.001

TABLE III. Total calculation times for CCSD/aug-cc-pVDZ ground state (t_{gs}), excitation energy (t_ω), and oscillator strength (t_{f_ω}) calculations for tryptophan. n_{calls}^{gs} is the number of calculations of the residual vector for the ground state. n_{calls}^R and n_{calls}^L are the number of calls to the Jacobian and Jacobian transpose transformations, respectively. The calculations were performed on an Intel Xeon E5-2699 v4 using 44 threads and 1.5 TB shared memory.

	t_{gs} (min)	t_ω (h)	t_{f_ω} (h)	n_{calls}^{gs}	n_{calls}^R	n_{calls}^L
Dalton 2018	1409	84	...	18	88	...
e^T 1.0	201	24	53	16	79	81
QChem 5.0	196	15	20	18	90	27

TABLE IV. The FC-CCSD/aug-cc-pVDZ correlation energy (E_{corr}) and lowest excitation energy (ω) of LSD. A set of decomposition thresholds (τ) for the Cholesky decomposition of the electron repulsion integral matrix were used. Both the ground and excited state equations are converged to within a residual threshold of 10^{-6} . Deviations in the correlation and excitation energies (ΔE_{corr} and $\Delta\omega$) are relative to $\tau = 10^{-8}$.

τ	E_{corr} (E_h)	ΔE_{corr} (E_h)	ω (E_h)	$\Delta\omega$ (E_h)
10^{-2}	-3.649 673 3	2.3×10^{-2}	0.165 734 3	7.1×10^{-4}
10^{-3}	-3.672 021 8	2.3×10^{-4}	0.165 037 0	7.7×10^{-6}
10^{-4}	-3.672 342 1	-9.2×10^{-5}	0.165 027 9	-1.4×10^{-6}
10^{-6}	-3.672 254 2	-3.6×10^{-6}	0.165 029 4	1.1×10^{-7}
10^{-8}	-3.672 250 6	...	0.165 029 3	...

We have performed FC-CCSD/aug-cc-pVDZ calculations on LSD ($n_{MO} = 777$, $n_{frozen} = 24$). To demonstrate the effect of integral approximation through Cholesky decomposition, we consider a range of decomposition thresholds. The correlation energy and the lowest excitation energy are given in Table IV. Both ground

and excited state residual thresholds are 10^{-6} . With a decomposition threshold of 10^{-2} , the error in the excitation energy ($\Delta\omega$) is less than $10^{-3}E_h$, well within the expected accuracy of FC-CCSD.^{74–76}

The CC3 model can be used to obtain highly accurate excitation energies. However, an iterative cost that scales as $\mathcal{O}(n_v^4 n_o^3)$ severely limits system size. To the best of our knowledge, e^T 1.0 includes the fastest available implementation of CC3. A ground and excited state calculation on glycine (chemical formula $C_2H_5NO_2$) using the aug-cc-pVDZ basis set took 33 min with e^T 1.0. Comparable numbers for the new²³ and old⁸⁰ CC3 implementations in Dalton 2018³ were 73 min and 1279 min, respectively.

We have calculated valence and core excitation energies and EOM oscillator strengths for the nucleobase uracil (chemical formula $C_4H_4N_2O_2$, see Fig. 3). The geometry was optimized at the CCSD(T)/aug-cc-pVDZ level using CFOUR.² One valence excitation energy was calculated at the FC-CCSD/aug-cc-pVTZ and FC-CC3/aug-cc-pVTZ levels of theory ($n_{MO} = 452$). Two core excited states were calculated for each of the oxygen atoms (O1 and O2, see Fig. 3) at the CCSD and CC3 levels. The aug-cc-pCVTZ basis was used on the oxygen being excited and aug-cc-pVDZ on the remaining atoms ($n_{MO} = 256$). The results are given in Table V. The total timings for the uracil calculations are presented in Table VI. In Table VII, we present the averaged timings from the CVS calculations. They clearly demonstrate the reduced computational cost of the CVS implementation for CC3. The ground state calculation was about four times more expensive per iteration than the right excited state. Without the CVS approximation, the computational cost of the excited states scales as $4n_v^4 n_o^3$ per iteration, while the ground state scales as $2n_v^4 n_o^3$. Using CVS, the excited state scaling is reduced to $4n_v^4 n_o^2$.

In Table VIII, we compare the timings for solving the ground and right excited state equations of glycine with aug-cc-pVDZ for different number of threads. All calculations were run on similar nodes, and all 40 cores on each node were reserved for the jobs to

FIG. 3. Uracil with labels on the oxygens.

TABLE V. CC3 valence and core (oxygen edge) excitation energies (ω) and EOM oscillator strengths (f_ω) for uracil. Valence excitations were calculated with the aug-cc-pVTZ basis on all atoms and the frozen core approximation. Core excitations were calculated using the CVS approximation with the aug-cc-pCVTZ basis on the oxygen atom being excited and the aug-cc-pVDZ basis on the remaining atoms.

	CCSD		CC3	
	ω (eV)	f_ω	ω (eV)	f_ω

TABLE VII. Average wall time per function call for both CC3 core excitation calculations on uracil. n_{calls} is the total number of routine calls in the two calculations.

Contributions	t (min)	n_{calls}
Ground state amplitudes	14	28
Ground state multipliers	23	30
Right excited states	4	195
Left excited states	7	244

minimize variation. Increasing the number of threads results in significant reductions in time, even for a relatively small system such as glycine with 20 occupied and 140 virtual orbitals. Intermediates are currently stored on disk, resulting in overhead that can be reduced by placing them in memory when possible. In addition to more adaptive memory usage, we are working on improving the coupled cluster algorithms for better parallelization.

B. Cholesky decomposition

We have determined the Cholesky basis for the transmembrane ion channel gramicidin A (chemical formula $C_{198}H_{276}N_{40}O_{34}$, see Fig. 4). The geometry is taken from the supplementary material of Ref. 81. Decomposition times are given in Table IX for the cc-pVDZ and aug-cc-pVDZ basis sets and a range of

TABLE VIII. Time to solve the ground and right excited state equations of glycine for CC3 and CCSD with different numbers of threads in seconds using a development version of e^T 1.1. Factor is the improvement compared to the row above. With perfect parallelization, the factors would be 5, 2, 2, and 2. The calculations were performed on nodes with two Intel Xeon Gold 6138 processors and 150 GB shared memory.

Threads	CC3 GS		CC3 ES		CCSD GS		CCSD ES	
	Time (s)	Factor	Time (s)	Factor	Time (s)	Factor	Time (s)	Factor
1	6048	...	15 617	...	639	...	654	...

decomposition thresholds. These are compared to the time of one HF iteration. Except when using cc-pVDZ with the tightest threshold, the decomposition time is small or negligible compared to one Fock matrix construction.

FIG. 4. Gramicidin A. The active MLHF/cc-pVDZ density is shown.

TABLE IX. Cholesky decomposition wall times (t) for gramicidin. τ is the decomposition threshold, and n_j is the number of Cholesky vectors. For reference, we include the time ($t_{\text{it}}^{\text{HF}}$) for one full Hartree–Fock iteration. All calculations were performed on an Intel Xeon E5-2699 v4 using 44 threads and 1.5 TB shared memory.

Basis	n_{AO}	τ	n_j	t (min)	$t_{\text{it}}^{\text{HF}}$ (min)
cc-pVDZ	5188	10^{-2}	11 574	3	35

C. Hartree-Fock

Systems with several hundred atoms are easily modeled in e^T using Hartree–Fock. In Table X, we present the wall times for calculations on gramicidin A (see Fig. 4) and an amylose chain with 16 glucose units (chemical formula $\text{C}_{96}\text{H}_{162}\text{O}_{81}$, see Fig. 5). The amylose geometry is taken from Ref. 24. We compare the results and timings from e^T 1.0 and QChem 5.0.¹¹ This comparison is complicated because the accuracy depends on several thresholds apart from the gradient and energy thresholds, e.g., screening thresholds and integral accuracy. Therefore, we list the energies and absolute energy differences along with the timings in Table X. QChem 5.0 outperforms e^T by about a factor of 2. The energies converge to slightly different results in the two programs. In the case of amylose, we find a $2 \times 10^{-7} E_h$ energy difference using the tightest thresholds ($\tau_{\text{SCF}} = 10^{-10}$). Since QChem is a closed source program, we do not know the reason for the deviation. However, we are able to reproduce the e^T results for amylose to all digits using tight thresholds in LSDalton 2018.³

D. Multilevel and multiscale methods

To demonstrate the efficacy of multilevel methods for excitation energies, we consider a system of sulfur dioxide with 21 water molecules (see Fig. 6). In Table XI, we present different flavors of multilevel calculations to approximate the two lowest FC-CC2 excitation energies for this system. Three sets of active atoms are defined. The first set contains sulfur dioxide and nine water molecules; these atoms determine the active orbitals of the MLHF calculation. The second set contains sulfur dioxide and five water molecules; these atoms determine the reduced space coupled cluster calculations. The third set contains only sulfur dioxide and determines the CC2 active space in the MLCC2 calculations. The reduced space FC-CC2 calculations are denoted FC-CC2-in-HF and FC-CC2-in-MLHF and similarly for the reduced space FC-MLCC2 calculations. The orbital spaces are partitioned using the Cholesky occupied orbitals and PAOs for the virtual orbitals. In all calculations, the deviation with respect to full FC-CC2 is within the expected error of CC2.^{75,76}

In order to assess the performance of the MLHF implementation, we compare full HF and MLHF for gramicidin A and amylose. The active electron densities from the MLHF calculations are shown

TABLE X. Hartree–Fock/cc-pVDZ calculations on amylose and gramicidin. The total wall time is denoted by t , and τ_{SCF} is the Hartree–Fock convergence threshold. We present timings for e^T and QChem along with the computed Hartree–Fock energies (E) and absolute energy differences ($|\Delta E|$) with respect to the calculation with the tightest threshold. Calculations were performed on two Intel Xeon E5-2699 v4 processors using 44 threads and 1.5 TB shared memory.

TABLE XII. Multilevel Hartree–Fock wall times for amylose and gramicidin. t_{it} is the wall time to construct the Fock matrix. For the calculations with (aug)-cc-pVDZ, aug-cc-pVDZ is used on the active atoms and cc-pVDZ for the rest. The total number of AOs and the active MOs is labeled n_{AO} and n_{MO}^{active} , respectively. Thresholds for Coulomb and exchange are set to 10^{-12} and 10^{-10} , respectively, and the integral cutoff is set to 10^{-12} . Calculations were performed on two Intel Xeon E5-2699 v4 processors using 44 threads and 1.5 TB shared memory.

	Basis	HF		MLHF	
		n_{AO}	t_{it} (min)	n_{MO}^{active}	t_{it} (min)
Amylose	cc-pVDZ	3288	8	335	1
	(aug)-cc-pVDZ	3480	11	552	4
Gramicidin	cc-pVDZ	5188	35	546	11
	(aug)-cc-pVDZ	5506	69	942	50

in Figs. 4 and 5. The plots were generated using UCSF Chimera.⁸² Cholesky orbitals were used to partition the occupied space, and PAOs were used for the virtual space. We present the timings in Table XII. For amylose, the iteration times are reduced significantly with MLHF: by a factor of 8 when cc-pVDZ is used on all atoms

and a factor of 3 when aug-cc-pVDZ is used on the active atoms. In contrast, only a factor of 3 was reported by Sæther *et al.*²⁴ in the cc-pVDZ case. The iteration time is also reduced by a factor of 8 for amylose/cc-pVDZ ($t_{iteration} = 1$ m, $n_{MO}^{active} = 318$) when using Cholesky virtuals (as in Ref. 24) instead of PAOs. The savings for amylose reflect the small active region as well as the linear structure of the chain. Savings are less significant for the gramicidin system, where the MLHF iteration time is a third of the HF iteration time for cc-pVDZ, but only about two thirds when the active atoms are described using aug-cc-pVDZ. The smaller savings reflect the relatively large active region and the more compact shape of the gramicidin system.

For systems in solution, electronic spectra can be calculated using QM/MM or QM/PCM. Paranitroaniline (PNA) has an experimental vacuum-to-water solvatochromism of about 1 eV.⁸⁷ For QM/PCM, we use two different atomic radii, UFF⁸⁵ (QM/PCM^c) and Bondi⁸⁶ (QM/PCM^d), and the dielectric permittivity of water was set to $\epsilon = 78.39$. For QM/MM, 64 snapshots were extracted from a classical molecular dynamics simulation⁸⁸ [see Fig. 7(a) for an example structure]. The UV/vis spectra were then computed by treating PNA at the CC2/aug-cc-pVDZ level and modeling the water using an FQ force field. Here, we present results using two different FQ parameterizations: QM/FQ^a from Ref. 83 and QM/FQ^b from

FIG. 7. (a) Schematic representation of a random snapshot of PNA in aqueous solution. (b) and (c) UV/vis spectra of PNA calculated at the CC2/aug-cc-pVDZ level of theory with an aqueous solution described at the PCM or FQ level of theory. (b) QM/FQ raw data (sticks) together with their Gaussian convolution (FWHM = 0.3 eV). (c) QM/PCM (top) and QM/FQ (bottom) spectra in aqueous solution. A gas phase CC2/aug-cc-pVDZ reference spectrum is also reported (black). For QM/FQ^a, the FQ parameterization is from Ref. 83, and for QM/FQ^b, the parameterization is from Ref. 84. In QM/FQ^c, the PCM cavity is constructed using the UFF radii,⁸⁵ and in QM/FQ^d, it is constructed using the Bondi radii.⁸⁶

TABLE XIII. The first vertical excitation energy of PNA in vacuum (ω_v) and in aqueous solution (ω_s), as well as water-to-vacuum solvatochromatic shifts ($\Delta\omega$). PNA is treated at the CC2/aug-cc-pVDZ level of theory, and the solution is described with PCM or FQ. 68% confidence intervals for excitation energies are also reported for QM/FQ, calculated as $\sigma/\sqrt{N}$, where σ is the standard deviation and N is the number of the snapshots used to obtain the average property. Experimental data are taken from Ref. 87.

	ω_v (eV)	ω_s (eV)	$\Delta\omega$ (eV)
CC2	4.38	...	...
CC2/FQ ^a	...	3.88±0.01	0.50±0.01
CC2/FQ ^b	...	3.38±0.01	1.00±0.01
CC2/PCM ^c	...	3.86	0.52
CC2/PCM ^d	...	3.76	0.62
Expt. ^e	4.25	3.26	0.99

^aFQ parameterization taken from Ref. 83.

^bFQ parameterization taken from Ref. 84.

^cPCM cavity constructed by exploiting UFF radii.⁸⁵

^dPCM cavity constructed by exploiting the Bondi radii.⁸⁶

^eReference 87.

Ref. 84 (see the [supplementary material](#) for additional computational details).

The spectra calculated using QM/FQ are presented in Fig. 7(b). The results for individual snapshots are presented as sticks together with their Gaussian convolution. As can be seen from Fig. 7, QM/FQ^b results in a greater spread in the excitation energies. This

is probably due to the larger molecular dipole moments of the water molecules in this parameterization.^{88,89}

In Fig. 7(c), the convoluted spectra calculated using QM/PCM^c and QM/PCM^d (top), and QM/FQ^a and QM/FQ^b (bottom), are presented with their vacuum counterparts. The excitation energies are also given in Table XIII together with the experimental data from Ref. 87. For QM/FQ, we also report 68% confidence intervals for the calculated excitation energies. QM/FQ^b reproduces the experimental solvatochromism, while the other approaches give errors of 40%–50%.

E. Modeling spectroscopies

The spectroscopic properties can also be modeled with the Lanczos method or with real-time propagation of the coupled cluster wave function. In Fig. 8, we show CCSD/aug-cc-pCVDZ UV/vis absorption spectra of H₂O,⁹⁰ calculated using the Davidson (top) and asymmetric Lanczos (bottom) algorithms. Note that we have artificially extended the spectra beyond the ionization potential (12.3 eV IP-CCSD/aug-cc-pCVDZ) to illustrate convergence behavior. With the Lanczos algorithm, the low energy part of the spectrum converges with a smaller reduced space than the high energy part.⁴⁷

We have also generated oxygen edge x-ray absorption spectra using the Davidson and Lanczos algorithms with CVS projection (see Fig. 9). We see the same overall behavior as in Fig. 8.

Absorption spectra can also be obtained from real-time propagation of the coupled cluster wave function (see Fig. 10 for UV/vis and oxygen edge x-ray absorption spectra; see the

FIG. 8. Water CCSD/aug-cc-pCVDZ UV/vis absorption spectrum. Lorentzian broadening ($0.02 E_h$ FWHM) has been applied to the stick spectra. The top plot shows the spectrum obtained using the Davidson. The spectrum in the bottom plot is from Lanczos calculations with chain lengths 100 (red), 200 (magenta), and 500 (blue).

FIG. 9. Water CCSD/CVS/aug-cc-pCVDZ x-ray absorption spectrum. Lorentzian broadening ($0.02 E_h$ FWHM) has been applied to the stick spectra. The top plot shows the spectrum obtained using the Davidson. The spectrum in the bottom plot is from Lanczos calculations with chain lengths 50 (red), 100 (magenta), and 500 (blue).

FIG. 10. Water UV and x-ray CCSD absorption spectra obtained using Davidson (CVS/aug-cc-pCVDZ for x ray and aug-cc-pVDZ for UV) and real-time propagation (aug-cc-pCVDZ for x ray and aug-cc-pVDZ for UV). The top and bottom plots show the simulated UV and x-ray spectra, respectively. The Davidson spectra were produced by applying Lorentzian broadening to the stick spectra ($0.0025 E_h$ FWHM). Intensities from the time-dependent simulation have been scaled so that the intensity of the first peak matches the EOM oscillator strength.

supplementary material for computational details). The first peak in both plots has been scaled to match the intensity obtained using Davidson. The position of the peaks are the same with both approaches, but the intensities differ because we specified pulses with frequency distributions centered on the first excitation energy.

IV. CONCLUDING REMARKS

e^T 1.0 is an optimized open source electronic structure program. Several features are worth emphasizing. To the best of our knowledge, our CC3 implementation is the fastest for calculating

ground and excited state energies and EOM oscillator strengths. The low memory CC2 code has memory and disk requirements of order $\mathcal{O}(n_{\text{MO}}^2)$ and $\mathcal{O}(n_{\text{MO}}^3)$, respectively, allowing us to treat systems with thousands of basis functions. At the core of our program is the Cholesky decomposition of the electron repulsion integral matrix; our implementation is faster and less storage intensive than that of any other program. Exciting new developments are also part of e^T . It features the only spin adapted closed shell implementation of time-dependent coupled cluster theory. Furthermore, the MLHF and MLCC2 methods extend the treatable system size without sacrificing accuracy for intensive properties such as excitation energies.

The e^T source code is written in modern object oriented Fortran, making it easy to expand and contribute to the program. It is freely available on GitHub,⁹¹ and the manual can be found at www.etprogram.org. We will continue to expand the capabilities of e^T , focusing on molecular properties and multilevel methods. We believe that the program will be useful for the quantum chemistry community, both as a development platform and for production calculations.

SUPPLEMENTARY MATERIAL

See the [supplementary material](#) for details regarding QM/MM calculations as well as specifications for the time-dependent CCSD propagation calculations.

AUTHOR'S CONTRIBUTIONS

S.D.F., E.F.K., and R.H.M. contributed equally to this work.

ACKNOWLEDGMENTS

We thank Sander Roet for useful discussions regarding Python and Git functionality. We thank Franco Egidi, Laura Grazioli, Gioia Marrazzini, Rosario Roberto Riso, and Anna Kristina Schnack-Petersen, who attended the e^T workshop in Pisa, October/November 2019. We also thank Edward Valeev for assistance with Libint and Roberto Di Remigio for help with a patch of PCMSolver. We acknowledge computing resources through UNINETT Sigma2—the National Infrastructure for High Performance Computing and Data Storage in Norway (Project Nos. NN2962k and NN9409k) and the SMART@SNS Laboratory. We acknowledge funding from the Marie Skłodowska-Curie European Training Network “COSINE—COMputational Spectroscopy In Natural sciences and Engineering” (Grant Agreement No. 765739) and the Research Council of Norway through FRINATEK Project Nos. 263110 and 275506. S.C. acknowledges support from the Independent Research Fund Denmark (DFF-RP2 Grant No. 7014-00258B).

DATA AVAILABILITY

The e^T source code is publicly available on Gitlab (see Ref. 91). The geometries used in Sec. III are available at <https://doi.org/10.5281/zenodo.3666109> (Ref. 73). Input files are available from the corresponding author upon request.
