Abstract

The European Commission asked EFSA to update their 2006 opinion on ochratoxin A (OTA) in food. OTA is produced by fungi of the genus *Aspergillus* and *Penicillium* and found as a contaminant in various foods. OTA causes kidney toxicity in different animal species and kidney tumours in rodents. OTA is genotoxic both *in vitro* and *in vivo*; however, the mechanisms of genotoxicity are unclear. Direct and indirect genotoxic and non-genotoxic modes of action might each contribute to tumour formation. Since recent studies have raised uncertainty regarding the mode of action for kidney carcinogenicity, it is inappropriate to establish a health-based guidance value (HBGV) and a margin of exposure (MOE) approach was applied. For the characterisation of non-neoplastic effects, a BMDL₁₀ of 4.73 µg/kg body weight (bw) per day was calculated from kidney lesions observed in pigs. For characterisation of neoplastic effects, a BMDL₁₀ of 14.5 µg/kg bw per day was calculated from kidney tumours seen in rats. The estimation of chronic dietary exposure resulted in mean and 95th percentile levels ranging from 0.6 to 17.8 and from 2.4 to 51.7 ng/kg bw per day, respectively. Median OTA exposures in breastfed infants ranged from 1.7 to 2.6 ng/kg bw per day, 95th percentile exposures from 5.6 to 8.5 ng/kg bw per day in average/high breast milk consuming infants, respectively. Comparison of exposures with the BMDL₁₀ based on the non-neoplastic endpoint resulted in MOEs of more than 200 in most consumer groups, indicating a low health concern with the exception of MOEs for high consumers in the younger age groups, indicating a possible health concern. When compared with the BMDL₁₀ based on the neoplastic endpoint, MOEs were lower than 10,000 for almost all exposure scenarios, including breastfed infants. This would indicate a possible health concern if genotoxicity is direct. Uncertainty in this assessment is high and risk may be overestimated.

Keywords: Ochratoxin, hazard characterisation, dietary exposure assessment, margin of exposure approach, risk characterisation

Requestor: European Commission

Question number: EFSA-Q-2018-00699

Correspondence: contam@efsa.europa.eu

Panel members: Margherita Bignami, Laurent Bodin, James Kevin Chipman, Jesús del Mazo, Bettina Grasl-Kraupp, Christer Hogstrand, Laurentius (Ron) Hoogenboom, Jean-Charles Leblanc, Carlo Stefano Nebbia, Elsa Nielsen, Evangelia Ntzani, Annette Petersen, Salomon Sand, Dieter Schrenk, Tanja Schwerdtle, Christiane Vleminckx and Heather Wallace.

Amendment: On page 75, before Figure 7, and on page 150, we have added text clarifying that the occurrence data for OTA on 73,891 food samples is available at the Zenodo link mentioned under the Annex section. On page 22 a chemical structure in Figure 6 has been revised to show the correct structure of the OTB-GSH conjugate. To avoid confusion, the original version of the document has been removed from the EFSA Journal, but is available on request, as is a version showing all the changes made.

Summary

Following a request from the European Commission, the European Food Safety Authority (EFSA) Panel on Contaminants in the Food Chain (CONTAM Panel) evaluated the risks to human health related to the presence of ochratoxin A (OTA) in food. The previous risk assessment of OTA from EFSA of 2006 was used as a starting point for the evaluation, together with publications identified in a targeted literature search. EFSA guidance documents and general principles for risk assessment were applied for hazard and exposure assessment and risk characterisation in this opinion.

OTA is produced by various fungi of the genus *Aspergillus* and *Penicillium*, e.g. *A. ochraceus*, *A. carbonarius* and *P. verrucosum*. OTA is stable to moderate heating, but losses ranging up to 90% are observed at temperatures above 180°C.

OTA is rapidly absorbed and distributed but slowly eliminated and excreted leading to potential accumulation in the body, which is due mainly to binding to plasma proteins and a low rate of metabolism. Plasma half-lives range from several days in rodents and pigs to several weeks in non-human primates and humans. The major metabolic pathway of OTA is hydrolysis to OTalpha, followed by conjugation with glucuronic acid. Formation of DNA-reactive metabolites is either minor or absent under physiological conditions. Based on efficient degradation in the rumen, OTA levels in cow milk are low. In several studies, relatively high OTA concentrations have been found in human milk in comparison with those found in cow milk.

A series of studies on biomarkers of exposure of humans to OTA, published after the latest EFSA evaluation, have been evaluated. It was found that dietary exposure to OTA was reflected in OTA levels in plasma, serum, urine and breast milk. Reliable biomarkers of OTA-specific effects, in particular kidney function, have not been identified.

The CONTAM Panel did not identify evidence suggesting that OTA is acutely toxic. OTA exerts adverse effects in repeated dose studies with mice, rats, rabbits and pigs. At high doses, various general signs of toxicity (e.g. reduced body and organ weights, changes in clinical chemistry) are observed. Also histopathological lesions, in particular in the kidney, immunotoxicity, neurotoxicity and developmental effects (associated with maternal toxicity) are observed. The critical effects occur in the kidney with the pig being the most susceptible species. In rats, kidney tumours have been observed in both sexes, with males being more sensitive. In mice, both liver and kidney tumours have been observed in both sexes albeit at higher doses as compared to the renal tumours in rats.

In vitro, OTA exposure induces gene mutations, single and double strand breaks (SSBs and DSBs) and chromosome damage in mammalian cells. This OTA-dependent genetic damage is apparently independent of metabolic activation. Exposure to OTA increases the levels of reactive oxygen species (ROS) *in vivo*, and *in vitro* exposure increases 8-hydroxydeoxyguanosine (8-OHdG) in DNA, both of which indicate that some genotoxic effects may be secondary to oxidative stress. *In vivo*, OTA-induced genetic damage (DSBs, aberrant mitoses and karyomegaly) is often associated with pathological findings in rat kidney. Gene mutations occurring in rats and mice are restricted to the cancer target site (the outer medulla of the kidney) with large deletions and base substitutions being the main mutagenic events. The molecular mechanisms underlying OTA genotoxicity *in vivo* remains unclear. OTA is a weak mutagen *in vivo*. Formation of covalent OTA-DNA adducts remains controversial and the extremely low levels of DNA-adducts reported do not explain the genotoxic effects of OTA. Nevertheless, OTA-induced mutations in rat and mouse kidneys are clearly not a simple consequence of oxidative DNA damage. The mechanisms underlying OTA-induced chromosomal damage are also unclear. Aberrant chromosome segregation and cell division may reflect damage to the mitotic spindle. Alternatively, abnormal anaphase figures might derive from un-resolved 'replication stress' with break-induced recombination of DSBs in the early stage of mitosis.

Possible associations between OTA exposure and kidney disease, bladder or hepatocellular cancer have been investigated in epidemiological studies using cross-sectional designs, but it is not possible to establish a causal link between exposure to OTA and adverse effects in humans. The findings of raised protein concentrations in urine in a limited number of infants from Egypt exposed to high levels of OTA *via* their mothers (during pregnancy and lactation) raise health concern and would need confirmation in larger studies.

Multiple molecular events of OTA have been reported, but the MoAs of OTA toxicity have not been clarified. The susceptibility of the kidney appears to be largely due to OTA uptake *via* the organic anion transporters in the kidney. With regard to the MoAs for kidney carcinogenicity in rats, induction of apoptosis and autophagy, cell cycle arrest, alterations in the cellular proliferation response and cell signalling, oxidative stress and changes in gene expression have each been proposed as contributing

factors. A role of genotoxicity in carcinogenesis cannot be excluded; however, a distinction between direct and indirect genotoxic modes of action which might each contribute to tumour formation could not be established.

Increased incidences of microscopic kidney lesions in a repeated dose study with female pigs have been identified as the critical non-neoplastic effect for risk characterisation and a BMDL₁₀ of 4.73 µg OTA/kg body weight (bw) per day was calculated from these effects and used as a non-neoplastic reference point (RP).

Increased incidences of kidney tumours seen in male rats in a 2-year study were identified as the critical neoplastic effect of OTA and a BMDL₁₀ of 14.5 µg OTA/kg bw per day was calculated from these effects and used as a neoplastic RP.

Since the previous EFSA assessment (2006), more recent studies have raised uncertainty regarding the mode of action for kidney carcinogenicity. Following respective EFSA guidance, the CONTAM Panel considered that it was not appropriate to establish an HBGV and concluded that for both non-neoplastic and neoplastic effects of OTA, an MOE approach needs to be applied for risk characterisation. As a consequence, the TWI of 120 ng/kg bw as established by the CONTAM Panel in 2006 is no longer valid.

For characterisation of chronic non-neoplastic effects, an MOE of ≥ 200 between the selected non-neoplastic RP and calculated exposures was considered as being of low health concern. This MOE was derived by applying a default uncertainty factor (UF) of 100 for intra- and interspecies toxicokinetic and toxicodynamic differences combined with an additional UF of 2 to account for extrapolation of a 3-month study in pigs to a chronic situation in that species.

For characterisation of chronic neoplastic effects, an MOE of $\geq 10,000$ between the selected neoplastic RP and calculated exposures would be of low health concern. This MOE was derived following EFSA guidance for substances that are both genotoxic and carcinogenic. In the interpretation of the MOE for the neoplastic risks, the Panel considered that the MOE of 10,000 for substances that are genotoxic and carcinogenic could be particularly conservative in this case because the evidence for a direct interaction of OTA with the DNA is inconclusive.

A total of 71,769 measurements of concentrations of OTA in food submitted within the last 10 years by 29 European countries and one Industry association were used for assessing dietary OTA exposures. The majority (about 55%) of the data came from Germany and the Netherlands. The proportion of left-censored data (results below the limit of detection (LOD) or limit of quantification (LOQ)) was 75%. The highest mean concentrations of OTA were recorded in the categories 'Plant extract formula', 'Flavourings or essences' (both containing liquorice extracts) and 'Chili pepper'.

For calculating chronic dietary exposure to OTA, food consumption and body weight data at the individual level were accessed in the EFSA Comprehensive Database. Mean occurrence levels and individual consumption data from different countries and age groups were linked at the relevant FoodEx level to estimate the chronic exposure.

The mean chronic exposure estimates ranged from 0.64 (minimum LB)/2.53 (minimum UB) to 9.13 (maximum LB)/17.79 (maximum UB) ng/kg bw per day across dietary surveys and age groups. The high (95th percentile) chronic dietary exposure estimates ranged from 2.40 (minimum LB)/5.13 (minimum UB) to 30.36 (maximum LB)/51.69 ng/kg (maximum UB) bw per day.

The most important contributors to the chronic dietary exposure to OTA were 'Preserved meat', 'Cheese' and 'Grains and grain-based products'. Dried and fresh fruits such as grapes, figs and dates as well as fruit juices and nectars were also contributing to the exposure of in some of the 'Toddlers' and 'Other children' groups, albeit, to a lesser extent than the three major categories. Non-chocolate confectionary was a significant source of exposure in countries where liquorice-based sweets are commonly consumed.

In a specific exposure scenario, occurrence data on OTA in breast milk in the public literature were used to assess the exposure of infants from breastfeeding (0–6 months of age). Based on the reported median concentration of OTA of 13 ng/L and a 95th percentile (P95) concentration of OTA of 43 ng/L in human milk (transitional and mature milk combined), the chronic dietary exposure to OTA ranged from 1.7 to 5.6 ng/kg bw per day for infants with an average milk consumption and from 2.6 to 8.5 ng/kg bw per day for infants with a high milk consumption.

The calculated MOEs for non-neoplastic effects ranged from 7,391 (LB Min in 'Infants') to 266 (UB Max in 'Toddlers') at mean exposures and from 1971 (LB Min in 'Very elderly') to 92 (UB Max in 'Toddlers'). Overall, they were above 200 in most of the dietary surveys for average and high consumers and therefore of low health concern and were below 200 at maximum LB in the age groups of 'Infants' and at maximum UB in the age group of 'Infants', 'Toddlers' and 'Other children' indicating

a possible health concern for these age groups. In breastfed infants, the MOEs were above 200 in all scenarios indicating a low health concern.

The calculated MOEs for neoplastic effects ranged from 22,615 (LB Min in 'Infants') to 815 (UB Max in 'Toddlers') at mean exposures and from 6,042 (LB Min in 'Very elderly') to 281 (UB Max in 'Infants'). With the exception of the minimum LB estimate for 'Infants' and 'Very elderly', the calculated MOEs for neoplastic effects were below 10,000 in most of the surveys, in particular for high consumers and breastfed infants indicating a possible health concern for these consumer groups.

For neoplastic effects of OTA, the CONTAM Panel emphasises, that it was not possible to make a clear distinction between a direct and an indirect mechanism of genotoxicity. As a result, the risk characterisation will be either not sufficiently cautious or overcautious depending on which MoAs actually take place. The Panel points out that the MOE of 10,000 is likely to be most conservative in this case as the evidence for a direct interaction of OTA with the DNA is inconclusive and alternative thresholded mechanisms may play a role in the formation of kidney tumours.

Pending elucidation of the MoAs for the genotoxicity/carcinogenicity of OTA, the Panel concluded that an MOE of 10,000 to the neoplastic reference point is warranted for the risk characterisation of OTA, albeit being the most conservative approach until the MoAs are clarified.

The overall uncertainty associated with the present assessment is considered as high. The assessment is more likely to overestimate than to underestimate the risk.

The CONTAM Panel recommended that more studies elucidating the sequence of critical events at the carcinogenic target site in the kidney are needed as well as more data on the levels of OTA in human milk and the differential toxicokinetics of OTA in different species including transfer to the fetus.

More information on the specific signature of OTA gene mutations in appropriate animal models is also needed. Reliable and representative investigations of the levels of OTA in human breast milk are needed. More occurrence data on OTA in cheese paste in comparison to cheese rinds are needed. More data on occurrence and toxicity of modified OTA are needed.

1. Introduction

1.1. Background and Terms of Reference as provided by the requestor

Background

Maximum levels for ochratoxin A are established at EU level for a wide range of foodstuffs.¹ Recently, findings of high levels of ochratoxin A are observed in food for which no maximum levels were set at EU level. Therefore, the possible setting of maximum levels for ochratoxin A in these foods was considered. During these discussions, certain delegations indicated that new toxicity studies have become available since the EFSA opinion of 2006.² It is therefore appropriate to request EFSA to assess these toxicity studies and to consider, if an update of the scientific opinion is necessary.

Terms of Reference

In accordance with Art. 29 (1) of Regulation (EC) No 178/2002, the European Commission asks the European Food Safety Authority to Authority to

- To assess the toxicity studies on ochratoxin A which have become available since the EFSA opinion on ochratoxin A in 2006 and to update the scientific opinion if necessary as regards hazard characterisation.
- To provide an updated exposure assessment taking into account recent occurrence data and the Comprehensive European Food Consumption Database.
- To update the section on risk characterisation, as necessary.

2. Additional information

2.1. Chemistry and formation of ochratoxin A

Ochratoxins are mycotoxins produced by various fungi of the genus *Aspergillus* and *Penicillium*, e.g. *A. ochraceus*, *A. carbonarius* and *P. verrucosum*. Their chemical structures contain the amino acid L-phenylalanine linked *via* an amide bond to a substituted dihydroisocoumaric acid (Figure 1). The most prevalent and toxic ochratoxin is ochratoxin A (OTA), which is the subject of this opinion. A notable feature of the OTA structure is the chlorine substituent (R^2 in Figure 1), which appears to be important for the toxicity of OTA. Ochratoxin B (OTB) is the non-chlorinated form of OTA, whereas ochratoxin C represents the ethyl ester of OTA (Figure 1). Other related mycotoxins formed at low levels by OTA-producing fungi are methyl esters of OTA and OTB, free dihydroisocoumaric acid (ochratoxin alpha, OTalpha see also Section 4.1.1 on Toxicokinetics) and amides of OTalpha with serine, hydroxyproline and lysine (Malir et al., 2016).

Ochratoxin	Substituents	Molecular formula	Molar mass (g · mol ⁻¹)	CAS number
OTA	$R^1 = H$; $R^2 = Cl$	$C_{20}H_{18}ClNO_6$	403.8	303-47-9
OTB	$R^1 = H$; $R^2 = H$	$C_{20}H_{19}NO_6$	369.4	4825-86-9
OTC	$R^1 = C_2H_5$; $R^2 = Cl$	$C_{22}H_{22}ClNO_6$	431.9	4865-85-4

Although the biosynthetic pathways of ochratoxins have not been established completely, it is known that the phenylalanine moiety originates from the shikimate pathway and the dihydroisocoumarin moiety from a polyketide (pentaketide) pathway (Heussner and Bingle, 2015).

OTA is a white, odourless, crystalline solid compound with melting point 168–173°C (Közsegi and Poor, 2016). It has a poor solubility in water (about 0.42 mg/L at 25°C) and a moderate solubility in polar organic solvents such as chloroform, ethanol and methanol. Due to its carboxylic group and phenolic hydroxyl group, OTA exists in non-ionic, monoanionic (OTA⁻) and dianionic (OTA²⁻) forms in aqueous solvents, depending on the pH. Its pKa values are 4.3 and 7.2. Due to its isocoumarin moiety, OTA exhibits a strong fluorescence after absorption of ultraviolet light, which depends strongly on the pH (Steinbrück et al., 2008). For details on the physico-chemical properties of OTA, including spectral data, see Pohland et al. (1982) and El Khoury and Atoui (2010).

2.1.1. Modified forms of OTA

Parent mycotoxins as produced by the fungi may undergo alterations of their chemical structure by chemical or biological reactions, e.g. during food processing or metabolism. Due to their altered structures, such modified mycotoxins are usually not detected by the analytical methods aimed at the parent toxins (Berthiller et al., 2013; Rychlik et al., 2014). However, these modified forms may contribute to the overall exposure and toxicity, if they are toxic in their own right or if they can release the parent toxin after absorption. Although OTA is quite stable to moderate heating (exhibiting for example only 30% reduction after dry heating to 150°C for 1 h), losses ranging from 70% to > 90% have been observed at temperatures above 180°C, such as used for coffee roasting (Cramer et al., 2008). Two OTA degradation products were identified by Cramer et al. (2008) in samples of roasted coffee: The major one was 2'R-OTA (Figure 2), which was originally reported as 14R-OTA and is the diastereomer of OTA. The second product is decarboxy-OTA (Figure 2) and constitutes only trace amounts compared to 2'R-OTA. More recently, OTalpha amide and OTA alpha (Figure 2) were identified as minor thermal degradation products of OTA (Bittner et al., 2013). The formation of OTA alpha amide had before been observed when OTA was exposed to light at 470 nm wavelength (Schmidt-Heydt et al., 2012), and OTalpha arises also from the hydrolysis of the peptide bond of OTA catalysed by numerous peptidases and lipases (Abrunhosa et al., 2010). Finally, Bittner et al. (2013) provided evidence for the covalent binding of OTA to coffee polysaccharides via esterification of its carboxyl group as a further thermal reaction. It is likely that some of the esters are hydrolysed during coffee brewing and the liberated OTA is released into the coffee brew, because higher amounts of OTA have been observed in brewed coffee than in roasted coffee beans (Studer-Rohr et al., 1995).

Figure 2: Modified forms of OTA arising from food processing

Although roasted coffee appears to be the major source of 2'R-OTA due to the high temperatures of > 120°C needed for its formation, small amounts of this isomerisation product of OTA have recently also been detected in malt coffee and in traditionally baked rye bread (Sueck et al., 2019).

In addition to OTA modifications occurring during food processing, OTA has also been shown to be metabolised by plants. Modified mycotoxins formed in plants are also termed 'masked' mycotoxins

(Rychlik et al., 2014). Ruhland et al. (1994, 1996a) demonstrated that (4S)- and (4R)-4-hydroxy-OTA and their monoglucosides are formed in wheat and maize cell suspension cultures (Figure 3). Moreover, OTalpha (see Figure 2) and the methyl esters of OTA and of both 4-hydroxy-OTA isomers (Figure 3) were detected, together with several minor unidentified metabolites. A nearly complete conversion of OTA to some of these metabolites was observed in cultures of several other crop plants (Ruhland et al., 1996b). OTalpha and the 4-hydroxy-OTA isomers were also identified in several vegetables and cereals after exposure of the plants to OTA (Ruhland et al., 1997). Therefore, modified forms of OTA may contribute to the health risk posed by this mycotoxin.

Another modified form of OTA is represented by OTC, the ethyl ester of OTA (see Figure 1). Fuchs et al. (1984) demonstrated that a single oral dose of OTC administered to rats gives rise to the same blood levels of OTA over 48 h as an equivalent dose of OTA, including the same maximum concentration of OTA 60 min after dosing. This implies that OTC is rapidly converted to OTA after oral administration.

Modified forms of OTA may also be formed as mammalian metabolites. For example, OTA glucuronides and sulfates have been reported (see Section 3.1.1 on Toxicokinetics), but in all these reports, OTA conjugates were determined indirectly by using enzymatic hydrolysis. No definite evidence for the formation of OTA conjugates and no complete structural characterisation are available. Likewise, conjugates of OTA with a hexose and pentose were described (see Section 3.1.1 on Toxicokinetics), but the structure elucidation of such OTA glycosides is still lacking.

Modified Form	Molecular formula	Molecular mass (g · mol ⁻¹)
(4S) 4-Hydroxy-OTA	C ₂₀ H ₁₈ ClNO ₇	419.8
(4R)-4-Hydroxy-OTA	C ₂₀ H ₁₈ ClNO ₇	419.8
(4S)-4-Hydroxy-OTA-β-D-glucoside	C ₂₆ H ₂₈ ClNO ₁₂	581.8
(4R)-4-Hydroxy-OTA-β-D-glucoside	C ₂₆ H ₂₈ ClNO ₁₂	581.8
OTA-methyl ester	C ₂₁ H ₂₀ ClNO ₆	417.8
(4S)-4-Hydroxy-OTA-methyl ester	C ₂₁ H ₂₀ ClNO ₇	433.8
(4R)-4-Hydroxy-OTA-methyl ester	C ₂₁ H ₂₀ ClNO ₇	433.8
OTalpha	C ₁₁ H ₉ ClO ₅	256.6

Figure 3: Modified forms of OTA arising from plant metabolism

2.1.2. Analytical methods

The analysis of OTA in food relies on well-established methods, and reliable results generally are obtained as evidenced by the results from proficiency testing.

Due to the chemical nature of the molecule, acid or alkali extraction from the matrix is commonly used. In general, alkaline extraction provides better recoveries; however, in the case of complex matrices (i.e. meat or sausages), an alkali–acid liquid–liquid partition can be used to increase selectivity.

Fluorescence-based methods, when positive results are obtained, are often followed by a confirmatory analysis based on OTA-methylation or OTA cleavage by carboxypeptidase treatment (Hult et al., 1979; Stander et al., 2001).

LC-MS methods are widely used for OTA, and usually cover OTB and minor metabolites such as OTalpha, as well (Hautbergue et al., 2017; Limay-Rios et al., 2017). Mass spectrometry is also extensively used for studying possible transformation occurring to the compound upon processing (Duarte et al., 2010; Bittner et al., 2013). The same approach based on LC-MS/MS is in use for modified forms of OTA originating upon processing (Bittner et al., 2013).

Classic analysis involves a C18 solid phase or immunoaffinity clean up prior to HPLC determination with fluorescence detection. Available validated methods cover almost all the possible foodstuffs, among them cereals (Spanjer et al., 2008; Desmarchelier et al., 2014), coffee (Drunday and Pacin, 2013; Nielsen et al., 2015; Chen et al., 2016; Kokina et al., 2016) and cocoa (Amézqueta et al., 2004), pork meat and sausages (Duarte et al., 2013; Brera et al., 2014), milk (Sørensen and Elbæk, 2005; Beltrán et al., 2011), dried fruits (Spanjer et al., 2008; Desmarchelier et al., 2014), wine (Visconti et al., 1999; Sáez et al., 2004; Rodríguez-Cabo et al., 2016), beer (Sáez et al., 2004; Ventura et al., 2006; Limay-Rios et al., 2017) and liquorice (Ariño et al., 2007; Lerda et al., 2013).

Over the past decade, OTA determination was included in the so-called 'multi-toxin' methods, based on LC-MS and covering hundreds of mycotoxins in the same analysis. The MS-based analysis of OTA is simple, with a good sensitivity and accuracy.

OTA and metabolites thereof are commonly analysed as biomarkers in biological fluids, such as blood, plasma, urine and tissues. Methods are based on LC-MS/MS using either direct detection (González-Arias et al., 2017; Sueck et al., 2019) or enzymatic cleavage (Ali et al., 2017; Muñoz et al., 2017).

When LC-MS is used, sample clean-up is often avoided, and a 'dilute-and-shoot' approach is adopted. In addition, confirmatory analysis is not required. Multi-toxin methods often suffer from lower accuracy and recoveries compared to single-analyte methods, due to the analytical compromise adopted to cover a wide spectrum of different compounds. However, parameters for OTA are usually of good analytical quality, as confirmed in proficiency testing (De Girolamo et al., 2013; Solfrizzo et al., 2013).

Besides chromatographic methods, immune-based analysis is often used for OTA determination (Barthelmebs et al., 2011; Cichna-Markl, 2011; Meneely and Elliott, 2014; Sun et al., 2017). A wide range of ELISA kits, dipsticks and lateral flow devices are commercially available, with established procedures for screening purposes. In the last decade, several biosensors have been proposed and implemented for rapid detection, often involving specific antibodies, aptamers or molecular imprinting polymers involved in the recognition process.

2.2. Previous risk assessments

In 2006, the EFSA CONTAM Panel published an opinion related to OTA in food (EFSA, 2006). The CONTAM Panel concluded that there is a lack of convincing evidence that Balkan Endemic Nephropathy (BEN) is associated with OTA exposure. OTA is nephrotoxic in all animal species tested and there is evidence that these effects are associated with oxidative stress. It also causes immuno- and neurotoxicity and teratogenicity at higher doses. OTA accumulates in the kidneys and upon chronic exposure to doses toxic to the kidney it also induces kidney and liver tumours in rodents. The results from genotoxicity tests are inconsistent. The overall evidence supports the hypothesis that DNA damage is induced by oxidative stress rather than by direct interaction. The Panel identified the effects on the kidneys in rats and pigs as the critical endpoint for OTA and established a tolerable weekly intake (TWI) of 120 ng OTA/kg bw based on an LOAEL of 8 µg/kg bw per day identified for early markers for renal toxicity in pigs and by applying a composite uncertainty factor (UF) of 450. This UF is composed of a default UF of 10 for intraspecies variability and a default UF of 2.5 for toxicodynamic and an OTA-specific UF of 6 for toxicokinetic interspecies variability (instead of the default 4.0) because the body burden resulting from the same external dose of OTA will be six times higher in humans than in pigs. An additional UF of 3 was used accounting for an LOAEL instead of an NOAEL. Main contributors to OTA dietary exposure were cereals and cereal products, wine, beer, grape juice, brewed coffee, cocoa and cocoa products and pork meat. Estimated exposure levels for average consumers varied between 15 and 20 ng/kg bw per week and for high consumers between 40 and 60 ng/kg bw per week and thus were below the TWI of 120 ng/kg bw. It was noted that these estimates are conservative for the adult population but that it cannot be excluded that infants and children and certain high consumers could have higher exposures.

The JECFA (Joint FAO/WHO Expert Committee on Food Additives) has issued several evaluations of OTA (FAO/WHO, 1991, 1996, 2001, 2008). In 1991, a provisional tolerable weekly intake (PTWI) of 112 ng/kg bw was established, based on an LOEL of 8 µg/kg bw per day for deterioration of renal function in pigs, and by application of an UF of 500. This UF was applied by the Committee because NOELs were frequently not demonstrated for OTA and the effects were observed already after a small proportion of a pig's lifetime and that consequently a 500-fold margin needs to be applied to the LOELs. In 1995, the PTWI was confirmed but rounded off to 100 ng/kg bw and was then retained in the JECFA evaluation that followed in 2002. In their most recent evaluation on OTA (FAO/WHO, 2008) in which new evidence and data becoming available since their last evaluation were considered, the JECFA again confirmed the PTWI of 100 ng OTA/kg bw. The estimates of dietary exposure to OTA using occurrence data (mainly from Europe) ranged from 8 to 17 ng/kg bw per week, and thus were well below the PTWI.

Health Canada have re-evaluated the appropriateness of the EFSA TWI to see if it would be applicable if OTA were to be regulated by a threshold approach and carried out a dietary risk assessment of OTA applying a non-threshold approach assuming that the compound is a genotoxic carcinogen (Kuiper-Goodman et al., 2010). Using the data on decreases in T_M (transport maximum) renal clearance expressed relative to body weight or to inulin clearance seen in a 90-day pig study (Krogh et al., 1974, 1979), they have derived a BMD_{10} (a benchmark dose defined as a 10% increase over the background) of 1.56 µg OTA/kg bw per day). Applying a default UF of 10 for intra-species variability and a default UF of 2.5 for toxicodynamic and a specific UF of 10 for toxicokinetic inter-species variability (instead of the UF of 6 used by EFSA) and a factor of 2 for extrapolating from a subchronic study to a chronic health-based guidance value (HBGV), a tolerable daily intake (TDI) of 3 ng/kg bw per day (which would correspond to a TWI of 21 ng/kg bw) was considered appropriate instead of the 17 ng/kg bw per day (corresponding to 120 ng/kg bw per week) as previously established by EFSA. For their risk assessment of OTA, Health Canada used a negligible cancer risk intake (NCRI) that was defined as the exposure associated with a cancer risk of 1:100,000. This is equivalent in units to a TDI derived using a tumourigenic dose 5% (TD_{05} , a 5% increase in incidence over background in the observable dose response curve) of 27.4 µg/kg bw per day from kidney tumours seen in a 2-year rat study. This value was corrected to 19.6 µg/kg bw per day considering that animals were dosed only 5 days per week (NTP, 1989). Applying a safety factor of 5,000 that results from dividing the TD_{05} by 5,000, which is equivalent to a 10^{-5} risk on a linear extrapolation to zero exposure, an NCRI of 4 ng OTA/kg bw per day resulted. Dietary exposures to OTA in a Canadian population were below the NCRI except for 1- to 4-year-old children.

In 2017, the UK Committee on Toxicity of Chemicals in Food Consumer Products and the Environment (COT) published a review of potential risks from OTA in the diet of infants aged 0–12 months and children aged 1–5 years (COT, 2018). The Committee evaluated all relevant *in vivo* studies published since the 2006 EFSA opinion and concluded that there is no new data available suggesting that the TWI of 120 ng/kg bw was established by EFSA in 2006, needs to be changed. Estimated exposure for breastfed infants ranged from 0.68 to 55 ng/kg bw per day for average consumers and from 1.02 to 82 ng/kg bw per day for high consumers. At low or average concentrations of OTA in breast milk exposures are below the TDI but at high concentrations infants estimated exposures exceeded the TWI by up to fivefold. The COT noted that such high exposures are unlikely to occur.

Mitchell et al. (2017) carried out a risk assessment of dietary OTA in the United States. For the risk characterisation, calculated exposures for different age groups in the 'total population' and 'consumers' (individuals reporting consumption of specific foodstuffs prone to contain OTA) were compared either with the JECFA PTWI of 100 ng/kg bw or the Health Canada NCRI of 4 ng/kg bw per day (for both HBGV values see text above in this section) and a margin of safety (MOS) approach was applied. Overall, MOS was > 1 in all age groups (both total population and consumers) applying either reference value. The only MOS ≤ 1 was seen when 95th percentile exposures of 'consumers' aged between 1 and 5 years were compared with the NCRI as established by Health Canada.

2.3. Legislation

Council Regulation (EEC) No 315/93³ stipulates that food containing a contaminant in an amount unacceptable for public health shall not be placed on the market, that contaminant levels should be

³ Council Regulation (EEC) No 315/93 of February 1993 laying down Community procedures for contaminants in food. OJ L 37, 13.2.1993, p. 1–5.

kept as low as can reasonably be achieved and that, if necessary, the European Commission may establish maximum levels for specific contaminants. These maximum levels are laid down in the Annex of Commission Regulation (EC) No 1881/2006⁴ and may include limits for the same contaminants in different foods, analytical detection limits and reference to the sampling and analysis methods to be used. Maximum levels for OTA have been established, for instance, for unprocessed cereals, dried vine fruits (currants, raisins and sultanas), green coffee, roasted coffee beans, ground roasted coffee, soluble coffee, wine and grape juice and range from 0.5 to 10 µg/kg. Commission Recommendation (EC) 2006/576/EC⁵ on the presence of deoxynivalenol, zearalenone, OTA, T-2 and HT-2 toxin and fumonisins in products intended for animal feeding provides guidance levels for OTA for feed materials and complementary and complete feedingstuffs ranging from 0.05 to 0.25 mg/kg.

3. Data and methodologies

3.1. Collection and appraisal of data collected from public literature

Following the terms of reference, the EFSA opinion of 2006 has been used as a starting point for the present assessment. On 26 July 2018, a literature search has been carried out for studies published in the period from 2006 to 2018. The databases used were Web of Science⁶ and Pubmed⁷ and references retrieved were managed using Endnote.⁸ The precise search terms for the different areas used are listed in detail in Appendix A.

Upon screening of the abstracts and by applying expert judgement, for the field of 'Mode of action', 156 publications were considered as potentially relevant for the assessment. The corresponding figures for the field of 'Toxicokinetics', were 37, for the field of 'Toxicity', they were 254 and for the field of 'Human evidence and biomarkers', they were 27. Studies dealing with compounds ameliorating the toxic effects of OTA have been included as potentially relevant. Studies on combined effects of OTA and other compounds have only been considered insofar they were potentially relevant for the assessment of OTA alone. Overall, the total number of publications considered as relevant in these fields was 451 and full-text originals were retrieved. In addition to these original studies also the previous assessments on OTA of JECFA (FAO/WHO, 2008), Kuiper-Goodman et al. (2010) and the UK COT (COT, 2018) and the studies referenced therein were considered for the present assessment. During the development of the opinion, additional publications were collected by applying a 'snowballing approach'⁹ and considered for the assessment where relevant.

3.2. Occurrence data submitted to EFSA

3.2.1. Data collection and validation

Following an European Commission mandate to EFSA, a call for annual collection of chemical contaminant occurrence data in food and feed, including OTA, was issued by EFSA's DATA unit (the former EFSA Dietary and Chemical Monitoring Unit) in December 2010 with a closing date of 1 October of each year. European national authorities and similar bodies, research institutions, academia, food business operators and other stakeholders were invited to submit analytical data on OTA in food and feed.

The data submission to EFSA followed the requirements of the EFSA Guidance on Standard Sample Description (SSD) for Food and Feed (EFSA, 2010a). Occurrence data were managed following the EFSA standard operational procedures (SOPs) on 'Data collection and validation' and on 'Data analysis of food consumption and occurrence data'.

Data on OTA in food available in the EFSA database from 2009 until the end of December 2018 were used for the present assessment. Data received after this date were not included in the present assessment.

⁸ EndNote X5, Thomson Reuters. <http://endnote.com/>

⁹ Identifying articles that have been cited in articles found in a search (see Jalali and Wohlin, 2012).

3.2.2. Data analysis

The data received were evaluated by EFSA and special attention was paid to the identification of duplicates and to the accuracy of different parameters, such as 'Analytical methods', 'Reporting unit' and the coding of the different samples under FoodEx classification. Upon identification of potential inconsistencies, data providers were contacted to provide further clarification.

The left-censored data (analytical data below the limit of detection (LOD) or limit of quantification (LOQ)) were treated by the substitution method as recommended in the 'Principles and Methods for the Risk Assessment of Chemicals in Food' (WHO/IPCS, 2009). The same method is described in the EFSA scientific report 'Management of left-censored data in dietary exposure assessment of chemical substances' (EFSA, 2010b) as an option for the treatment of left-censored data. The guidance suggests that the lower bound (LB) and upper bound (UB) approach should be used for chemicals likely to be present in the food. At the LB, results below the LOQ or LOD were replaced by zero; at the UB, the results below the LOD were replaced by the numerical values of the LOD and those below the LOQ were replaced by the value reported as LOQ.

The use of different cut-off values on the reported LOQs was also evaluated in order to reduce the uncertainty associated with the exposure estimations (Annex, Tables 2 and 5).

For certain chemical contaminants such as mycotoxins, it is common to have a high percentage of left-censored data in several food groups. Existing maximum levels (MLs) in Commission Regulation (EC) No 1881/2006⁴ have been used in the corresponding food categories as cut-off values for the LOQs so that results obtained with analytical methods with an LOQ higher than the MLs were not included. In addition, in those food groups which are important sources of dietary exposure, the distribution of the reported LOQ was assessed, and a cut-off value was selected based on selected percentiles (see Table 12) to eliminate extreme high LOQs.

3.3. Food consumption data

The EFSA Comprehensive European Food Consumption Database (Comprehensive Database) provides a compilation of existing national information on food consumption at individual level and was first built in 2010 (EFSA, 2011a; Huybrechts et al., 2011; Merten et al., 2011). Details on how the Comprehensive Database is used are published in the Guidance of EFSA (EFSA, 2011a). The latest version of the Comprehensive Database, updated in 2018, contains results from a total of 60 different dietary surveys carried out in 25 different Member States covering 119,458 individuals.

Within the dietary studies, subjects are classified in different age classes as follows:

Infants:	< 12 months old
Toddlers:	≥ 12 months to < 36 months old
Other children:	≥ 36 months to < 10 years old
Adolescents:	≥ 10 years to < 18 years old
Adults:	≥ 18 years to < 65 years old
Elderly:	≥ 65 years to < 75 years old
Very elderly:	≥ 75 years old

Four additional surveys provided information on specific population groups: 'Pregnant women' (≥ 15 years to ≤ 45 years old, Latvia; 17 years old to 46 years old, Portugal) and 'Lactating women' (≥ 28 years to ≤ 39 years old, Greece; 18 years old to 45 years old, Estonia).

For chronic exposure assessment, food consumption data were available from 53 different dietary surveys carried out in 22 different European countries. When for one particular country and age class two different dietary surveys were available, only the most recent one was used. This resulted in a total of 38 dietary surveys selected to estimate chronic dietary exposure.

In Table 4 of the Annex, these dietary surveys and the number of subjects available for the acute and chronic exposure assessment are described.

The food consumption data gathered by EFSA in the Comprehensive Database are the most complete and detailed data currently available in the EU. Consumption data were collected using single or repeated 24- or 48-h dietary recalls or dietary records covering from 3 to 7 days per subject. Because of the differences in the methods used for data collection, direct country-to-country comparisons can be misleading.

3.4. Food classification

Consumption and occurrence data were classified according to the FoodEx classification system (EFSA, 2011b). FoodEx is a food classification system developed by EFSA in 2009 with the objective of simplifying the linkage between occurrence and food consumption data when assessing the exposure to hazardous substances. The system consists of a large number of individual food items aggregated into food groups and broader food categories in a hierarchical parent-child relationship. It contains 20 main food categories (first level), which are further divided into subgroups having 140 items at the second level, 1,261 items at the third level and reaching about 1,800 endpoints (food names or generic food names) at the fourth level.

3.5. Methodology for exposure assessment

The CONTAM Panel considered that only chronic dietary exposure had to be assessed. As suggested by the EFSA Working Group on Food Consumption and Exposure (EFSA, 2011c), dietary surveys with only one day per subject were not considered for chronic exposure as they are not adequate to assess repeated exposure. Similarly, subjects who participated only one day in the dietary studies, when the protocol prescribed more reporting days per individual, were also excluded for the chronic exposure assessment. Not all countries provided consumption information for all age groups, and in some cases the same country provided more than one consumption survey.

For calculating chronic dietary exposure to OTA, food consumption and body weight data at the individual level were accessed in the Comprehensive Database. Occurrence data and consumption data were linked at the relevant FoodEx level.

The mean and the high (95th percentile) chronic dietary exposures were calculated by combining mean occurrence values for each food collected in different countries (pooled European occurrence data) with the average daily consumption of each food at individual level in each dietary survey and age class. Consequently, individual average exposures per day and body weight were obtained for all individuals. Based on the distributions of individual exposures, the mean and 95th percentile exposures were calculated per survey and per age class. Dietary exposure was assessed using overall European LB and UB mean occurrence of OTA. All analyses were run using the SAS Statistical Software (SAS enterprise guide 7.15).

In the present assessment, occurrence levels above the MLs as laid down in Commission Regulation (EC) No 1881/2006 have been considered as the occurrence data sampled from products which are actually on the market. This is in accordance with the general principles of EFSA exposure assessments. To evaluate their impact on the overall assessment, an ad hoc scenario with the exclusion of non-compliant samples was carried out which showed only a very minor impact on the exposure results (see Section 4.11.2).

3.6. Methodology for risk characterisation

The CONTAM Panel applied the general principles of the risk assessment process for chemicals in food as described by the WHO/IPCS (2009), which include hazard identification and characterisation, exposure assessment and risk characterisation. Additional to the principles described by the WHO/IPCS (2009), EFSA guidance pertaining to risk assessment has been applied for the present assessment. The EFSA guidance covers the procedures currently used within EFSA for the assessment of dietary exposure to different chemical substances and the uncertainties arising from such assessments. EFSA guidance documents applied in the present opinion are the guidances on approaches for the assessment for substances that are both genotoxic and carcinogenic (EFSA, 2005; EFSA Scientific Committee, 2012b), uncertainties in dietary exposure assessment (EFSA, 2007), transparency in scientific aspects of risk assessments (EFSA, 2009), standard sample description for food and feed (EFSA, 2010a), management of left-censored data in dietary exposure assessments (EFSA, 2010b), use of the EFSA comprehensive food consumption database in intakes assessment (EFSA, 2011a), procedures used for dietary exposure assessment (EFSA, 2011b), evaluation of FoodEx (EFSA, 2011c), genotoxicity testing (EFSA Scientific Committee, 2011), selected default values to be used in the absence of data (EFSA Scientific Committee, 2012a), risk assessment terminology (EFSA Scientific Committee, 2012b) and on the use of the benchmark dose approach (EFSA Scientific Committee, 2017).

4. Assessment

4.1. Hazard identification and characterisation

4.1.1. Toxicokinetics

In 2006, EFSA characterised the toxicokinetics of OTA as follows: OTA is rapidly absorbed after oral ingestion with a bioavailability ranging from 40% to 66% depending on the species and the dose. In the systemic circulation, OTA is extensively (up to 99.98% in humans) bound to albumin and other serum proteins, which gives rise to long elimination half-lives in blood (3–10 days in various rat strains, 5–6 days in pigs, 19–21 days in non-human primates and up to 35 days in one human individual). In rodents, the major route of excretion is *via* bile and faeces, whereas renal excretion prevails in other species including monkeys and humans. Although a few hydroxylated and conjugated metabolites of OTA have been described *in vitro* and *in vivo*, biotransformation of OTA in general appears to be low and restricted mostly to hydrolysis of the amide bond leading to OTalpha *in vivo*. A striking feature observed in *in vivo* animal studies is the accumulation of OTA in kidneys, associated with marked differences between species and sexes. Both organic anion transporters (OAT¹⁰) and members of the ATP-dependent transporter family appear to be involved in the uptake of OTA into renal cells and its efflux (EFSA, 2006).

Toxicokinetic studies on OTA conducted more recently, i.e. after 2006, have confirmed the earlier observations. The following chapters will discuss the toxicokinetics of OTA in more detail with an emphasis on recently published data. For recent reviews, see Ringot et al. (2006), Vettorazzi et al. (2014) and Kőszegi and Poor (2016).

4.1.1.1. Absorption

After oral ingestion, OTA is rapidly absorbed in several animal species, reaching peak blood levels within a few hours. For example, in a recent study in male SD rats using LC-MS technology and ¹³C-labelled OTA as internal standard, a peak concentration of 1.9 µg OTA/mL blood plasma was reached 4.8 h after oral gavage of a single dose of 0.2 mg OTA/kg bw, followed by a decrease with a half-life of 76 h (Han et al., 2013a). Systemic availability via passive diffusion from the stomach and particularly from the proximal jejunum is believed to be greatly facilitated by the high binding affinity of OTA to plasma proteins (see Section 4.1.1.2 on Distribution). Absorption from the jejunum can take place against a concentration gradient and appears to involve a transport by OAT in addition to passive diffusion. The bioavailability of OTA is in the range of 50%, e.g. 66% in pigs, 56% in rats and rabbits and 40% in chicken in the study by Galtier et al. (1981) and depends mainly on the species, dose, vehicle and presence of food in the stomach at the time of OTA administration. In a male adult volunteer with an empty stomach ingesting tritium-labelled OTA at a dose of 0.02 nmol/kg bw, 93% of the administered radioactivity was found in the blood within 8 h of ingestion, with 4–10% of the radioactivity in the blood located in the erythrocytes and over 90% in the plasma (Studer-Rohr et al., 2000).

4.1.1.2. Distribution

A major characteristic of OTA in humans and many animal species is its very high non-covalent binding to serum proteins, particularly to albumin. After an oral dose of 50 ng OTA/g bw, only 0.02% of the OTA in blood remained unbound in humans, 0.08% in monkeys, 0.1% in mice and pigs, but 22% in fish (Hagelberg et al., 1989). The high binding to serum proteins facilitates absorption of OTA but delays its elimination from blood and its excretion and explains the long half-life of OTA in the body. After a single oral dose of tritium-labelled OTA, a fast elimination from plasma with a half-life of about 20 h was observed in humans during the first 6 days, followed by a much slower elimination phase with a half-life of 35 days and a renal clearance of about 0.1 mL/min (Studer-Rohr et al., 2000). Mantle (2008) reported considerable strain differences in the plasma half-life of OTA, ranging from 8 to 10 days in Fischer rats to 2–3 days in Dark Agouti rats. The influence of the plasma protein binding of OTA is illustrated by the observation that the half-life of OTA in albumin-deficient rats was much shorter than in normal rats and that the concentration of OTA in bile and urine was 20- to 70-fold higher in the deficient animals than in control rats (Kumagai, 1985). OTA interacts with albumin as a dianion, and two binding sites for OTA were identified on human serum albumin (Perry et al., 2003).

¹⁰ OATs are a subgroup of solute carriers (SLCs).

The differences between species in the binding of OTA to plasma albumin have a profound impact on the proportion of free (unbound) OTA in plasma. For instance, using the different binding constants for Wistar rats ($4.0 \times 10^4 \text{ M}^{-1}$), pigs ($7.1 \times 10^4 \text{ M}^{-1}$) and humans ($5.2 \times 10^6 \text{ M}^{-1}$) as reported by Perry et al. (2003), and assuming the same total plasma concentration of 10 nM OTA (bound plus unbound OTA), the concentration of free OTA in plasma is 400 pM in rats, 230 pM in pigs and 3.2 pM in humans. For the calculation of these values, see Appendix D, and for their consideration in deriving uncertainty factors, see Section 4.6 on Establishment of a HBGV vs. application of an MOE approach.

OTA is distributed into every organ, although the concentrations of the toxin appear to depend on the animal species, the dose administered and the design of the kinetic study. Many studies report the highest concentrations in the kidney, followed by liver and muscle. After removal of residual blood from organs, Zepnik et al. (2003) found 40-, 100-, and 270-fold higher concentrations of OTA in rat kidney than in rat liver at 24 h, 48 h and 72 h after a single oral dose of 0.5 mg OTA/kg bw. In the study by Han et al. (2013a), the order of tissues with the highest OTA concentrations were kidney > lung > liver = heart > spleen > brain after a single oral dose of 0.2 mg OTA/kg bw; all tissue levels peaked at 4 h after dosing. After repeated doses, levels in kidney and liver tend to be more similar. In addition, redistribution and deposition of OTA in lipid-rich organs may occur. For example, when OTA was orally administered to male Sprague-Dawley rats at a daily dose of 0.1 mg/kg bw for 20 days, the concentration of OTA was somewhat higher in the lung ($96 \pm 14 \text{ ng/g}$ wet weight) than in the liver (76 ± 10), followed by heart (62 ± 4), kidney (56 ± 5), spleen (25 ± 2) and brain (4 ± 1) (Han et al., 2013a). The ratio of OTA levels in kidney to liver was about 2 after 4 h of a single dose and 0.7 after repeated dosing for 20 days (Han et al., 2013a). When male and female Dark Agouti rats were fed a diet containing four different concentrations of OTA (ranging from 2.5 to 100 μg per kg diet) for 28 days, the lung was found to contain the highest concentration of OTA, with slightly lower levels in the liver and about half the lung concentration in the kidney (Tozlovanu et al., 2012).

In order to determine placental transfer of OTA, the kinetics of tritium-labelled OTA was studied in human perfused term placenta (Woo et al., 2012). Only minimal passage of OTA through the placenta was observed in this *in vitro* study and the fetal/maternal ratio of OTA at the end of the perfusions (up to 20 h) was only about 0.02. Further studies showed that inhibition of the placental efflux transporters ABCG2 and ABCC2 did not increase the transfer of OTA to the fetal circulation (Woo et al., 2012). However, several studies showed *in utero* transfer in mammalian species such as rat, mouse and swine (Ringot et al., 2006 and literature cited therein). Differences in fetal uptake of OTA were observed in mice after different durations of gestation, suggesting that the transfer is influenced by the developmental stage of the placenta. In individuals from Switzerland and Poland eating a normal diet, OTA concentrations in placenta and fetal serum were found to be about twice as high as in maternal serum, and the involvement of placental OATs have been proposed to explain this active placental transfer (Zimmerli and Dick, 1995; Postupolski et al., 2006).

OTA is also transferred to breast milk in animals and humans. The results of some animal studies have been reviewed by Ringot et al. (2006). A low milk/plasma ratio of 0.015 was observed with lactating rabbits fed a naturally contaminated diet, and the concentration of OTA in milk did not change throughout the lactation period. No OTA was detected in the milk of lactating sows on a naturally contaminated diet. In contrast, studies in lactating rats receiving a single oral dose of OTA or repeated doses over 8 weeks showed a milk to blood concentrations of OTA ranging between 0.4 and 0.7. The transfer of OTA into human milk is lower (0.2) and is discussed in detail in Section 4.1.1.4.1. Only trace amounts of OTA are commonly detected in the milk of cows, which is the major provider of dairy products in human nutrition; this is attributed to the efficient presystemic degradation of OTA by the ruminal microflora, as described in Section 4.1.1.6.

4.1.1.3. Metabolism

The recent report by Wu et al. (2011) reviews extensively the metabolism of OTA in various animal species, humans, plants and microorganisms. The established biotransformation pathways in animals and humans are presented in Figure 4. For references, see Wu et al. (2011). For details of studies on the biotransformation of OTA in *in vitro* systems, in animals *in vivo* and in humans see Appendix E, Tables E.1, E.2 and E.3, respectively.

Figure 4: Metabolic pathways of OTA in animals and humans

The major OTA metabolite is OTalpha, which is formed when the amide bond between phenylalanine and dihydroisocoumaric acid is hydrolysed. OTalpha has first been found in the caecum and large intestine of rats and in the excreted faeces after oral administration of OTA. It is believed to be mostly generated by the intestinal microbiome in non-ruminants including humans (Ali et al., 2017) and by the rumen microbiome in cows, sheep and other ruminants. The degradation of OTA to OTalpha is catalysed by numerous hydrolases, among which carboxypeptidase A appears to be particularly active. The formation of OTalpha is considered as an important detoxification pathway of OTA. Although partly absorbed from the intestine, OTalpha does not accumulate in the kidney but is rapidly excreted with the urine, also as a glucuronide. In humans, OTalpha-glucuronide is a major urinary metabolite.

Cytochrome P450-mediated hydroxylation, a common phase I metabolic reaction of many lipophilic compounds, has also been demonstrated for OTA. The respective metabolites are 4-hydroxy-OTA and 10-hydroxy-OTA. Because of the chirality of the C-4 atom of 4-hydroxy-OTA, two stereoisomers (4R and 4S) are formed. These metabolites are consistently formed in microsomal incubations and in cell cultures *in vitro* (see Appendix E, Table E.1), and have also been detected in some studies at very low levels in urine of rats treated with OTA (see Appendix E, Table E.1). Overall, *in vitro* and *in vivo* studies on OTA biotransformation show that hydroxylation of the isocoumarin moiety plays only a minor role in OTA metabolism.

In addition to these well-established hydrolytic and oxidative pathways of OTA, several other phase I and phase II biotransformation pathways have been proposed. These include i) hydroxylation of OTA at the phenylalanine moiety, ii) opening of the lactone ring, iii) dechlorination of OTA leading to OTB, a hydroquinone (OTHQ)/quinone (OTQ) redox couple and corresponding glutathione-S (GSH)-conjugates, and iv) conjugation with a hexose and pentose, glucuronic acid and sulfate. These pathways are discussed in more detail below.

4.1.1.3.1. Hydroxylation at the phenylalanine moiety

Besides hydroxylation of the isocoumarin moiety of OTA, a recent study suggests that OTA may also be hydroxylated at the phenylalanine moiety. Using LC-MS/MS analysis of liver microsomal incubations and urine and faeces samples obtained from rat and chickens exposed to OTA, Yang et al. (2015) detected three further hydroxylated metabolites in addition to 4(R)- and 4(S)-hydroxy-OTA and tentatively identified these as 9'-hydroxy-OTA, 7'-hydroxy-OTA, and 5'-hydroxy-OTA based on mass spectral data. Synthetic reference compounds to support the chemical structure of the proposed metabolites and to allow quantitative analysis were not available.

4.1.1.3.2. Lactone ring opening

A metabolite with an open lactone ring (OP-OTA) has been detected in urine and bile of rats dosed with OTA (Xiao et al., 1996; Li et al., 2000). The high toxicity of this metabolite may be due to its ability to undergo reversion of lactone ring opening, which would lead to OTA.

4.1.1.3.3. Dechlorination of OTA and conjugation with GSH

Electrochemical and photochemical reaction of OTA has been shown to generate an OTHQ/OTQ redox couple (Figure 5) that may react with tissue nucleophiles (Calcutt et al., 2001; Dai et al., 2002). This reaction involves loss of the chlorine atom and presumably proceeds via an aryl radical, which may also form OTB (Manderville, 2005; Pfohl-Leszkowicz and Manderville, 2012). Whether dechlorination of OTA leading to formation of OTB, OTHQ and OTQ and associated GSH-conjugates can also occur under physiological conditions is of key interest as this may indicate formation of reactive metabolic intermediates and may thus have a bearing on the question of OTA genotoxicity. OTB has been repeatedly reported as a minor metabolite of OTA (usually in the range of 1% of OTA) *in vitro* (El Adlouni et al., 2000; Faucet-Marquis et al., 2006; Yang et al., 2015) (see Appendix E, Table E.1) and *in vivo* (Mally et al., 2004; Yang et al., 2015) (see Appendix E, Table E.2). However, because the OTA used in metabolic studies is invariably of fungal origin and only very rarely analysed for OTB, it is difficult to discriminate the OTB introduced as contaminant of OTA from OTB potentially arising from the metabolism of OTA. Han et al. (2013b), when studying the microsomal glucuronidation of OTA *in vitro*, detected OTB both in active and in control incubations in similar amounts as found in the standard solution of OTA and concluded that the OTB was the impurity from the standard and not formed as a metabolite. LC-MS/MS analyses of OTA from a commercial source and another laboratory showed the presence of about 1% OTB (personal communication, Angela Mally, University of Würzburg). A metabolite suggested by the authors to be OTHQ was detected in kidney cells *in vitro* (Faucet-Marquis et al., 2006) and in rat urine (Mally et al., 2004). Both studies also reported the presence of OTB. Since 4-hydroxy-OTB, which is a metabolite of OTB, differs from OTHQ only in the position of the hydroxyl group and has the same mass, mass fragmentation pattern and similar chromatographic conditions as OTHQ (Mally et al., 2005c), it is possible that 4-hydroxy-OTB may be mistaken for OTHQ. In contrast to 4-hydroxy-OTB, OTHQ is unstable in the presence of oxygen and is easily oxidised to OTQ, which itself decomposes in aqueous solution to several products (Gillman et al., 1999) and must be expected to react with nucleophilic components of biological materials, e.g. GSH. OTQ itself has not been found to date in metabolic studies *in vivo* or *in vitro*.

Figure 5: Hypothetical reactive metabolites of OTA and their products

The proposed reactive metabolites include (1) an aryl radical formed from OTA by reductive dechlorination, (2) a phenoxyl radical formed from OTA by one-electron oxidation and (3) OTQ formed from OTA by oxidation mediated by peroxidases or cytochrome P450.

Dai et al. (2002) first reported that OTHQ photoreacted with GSH to a product identified by mass spectrometry (MS) and nuclear magnetic resonance (NMR) spectroscopy as OTHQ with a covalently bonded GSH at C-6 (Figure 6); this OTHQ-GSH conjugate was formed in about 1% yield in incubations of OTA with rat liver microsomes/NADPH or horseradish peroxidase/H₂O₂ or free Fe²⁺. While other

reports found no evidence for formation of GSH-conjugate *in vitro* (Gautier et al., 2001; Gross-Steinmeyer et al., 2002) or *in vivo* (Gautier et al., 2001; Zepnik et al., 2003). Tozlovanu et al. (2012) reported the detection of OTHQ-GSH in livers and kidneys of male and female Dark Agouti rats dosed with 100 µg/kg bw per day for 28 days. In the same studies, another GSH conjugate was detected which carries the GSH at C-5 of OTA (Figure 6), thus replacing the chlorine atom and therefore named OTB-GSH; the amount of OTB-GSH exceeded that of OTHQ, particularly in the kidney of male rats. GSH conjugates are degraded to their corresponding N-acetyl-L-cysteine (NAC) conjugates (also termed mercapturic acids) in the kidney prior to renal excretion. In a very recent study using LC-MS/MS analysis and authentic reference compounds, OTB-NAC (Figure 6) has been reported to occur in the urine of 11 out of 18 male and female volunteers (Sueck et al., 2020). No correlation between the urinary concentration of OTB-NAC and OTA was observed.

Figure 6: Conjugates of OTA metabolites with GSH and their corresponding mercapturic acids

4.1.1.3.4. Further OTA-derived conjugates

The formation of glucuronic acid and sulfate conjugates in OTA metabolism has so far been concluded from the fact that more OTA could be detected after treatment with β -glucuronidase and aryl sulfatase. In a more recent *in vitro* study with rat liver microsomes, small amounts of all three possible glucuronides of OTA, i.e. with the glucuronic acid located at the phenolic hydroxyl group (C-8), the carboxyl group (C-1') and the amide group, were tentatively identified by mass spectrometry (Han et al., 2013b). Moreover, OTA-methyl ester, OTalpha and OTalpha glucuronide were detected in this study.

OTA conjugates with a hexose and a pentose have been identified in incubations of OTA with rat and human hepatocytes (Gross-Steinmeyer et al., 2002) and in the urine of OTA-treated rats (Zepnik et al., 2003) based on evidence from LC-MS/MS, but the exact chemical structures are yet unknown.

4.1.1.3.5. Summary of OTA metabolism

With the exception of hydrolysis of the peptidic bond of OTA leading to OTalpha (which occurs mainly in the intestine), all the described biotransformation reactions appear to represent minor pathways in the mammalian metabolism of OTA. For example, when rats were administered a single low dose of OTA and urine, faeces, blood, liver and kidney were analysed by a sensitive LC-MS/MS method, OTalpha mainly as a glucuronic acid conjugate was detected as the major OTA metabolite in urine and faeces, together with low concentrations of OTA-hexose and OTA-pentose in urine (Zepnik et al., 2003). OTalpha was also detected in blood but not in liver and kidney. 4- and 10-Hydroxy-OTA,

lactone ring open OTA, glutathione and glucuronide conjugates were not present in urine, blood, liver or kidney in detectable concentrations (Zepnik et al., 2003). These data are in good agreement with detection of OTalpha, 4(R)-OH-OTA and two unidentified metabolites in urine of male rats administered uniformly labelled [³H]OTA (Gautier et al., 2001). The unidentified metabolites did not correspond to OP-OTA, 4(R)-hydroxy-OTA or OTB and may be identical to the OTA-hexose- and pentose derivatives as judged by their chromatographic behaviour.

In another study with tritium-labelled OTA in a male human, > 80% of the radioactivity in blood was unchanged OTA and no metabolites were observed. In urine, about 50% was OTA and the rest was probably metabolites, which however were not further characterised (Studer-Rohr et al., 2000).

Overall, the rate of *in vivo* biotransformation of OTA in non-ruminant animals and in humans appears to be low.

A critical and much disputed question is whether OTA can be activated to electrophilic metabolites capable of covalent binding to DNA and other cellular macromolecules. The potential formation of such genotoxic metabolites is highly relevant for risk assessment of this carcinogenic mycotoxin. Several pathways have been proposed for the metabolic activation of OTA (Manderville, 2005; Manderville and Wetmore, 2017) as depicted in Figure 5. However, formation of reactive metabolites capable of covalent binding to DNA, such as those demonstrated in photochemical and iron-containing systems, appears to be very minor or absent under physiological conditions. (Appendix E, Tables E.1 and E.2). For example, *in vitro* studies by Gautier et al. (2001) showed the formation of 4R-hydroxy-OTA upon incubation of OTA with rat or human liver microsomes, but no evidence for oxidative metabolites was found with rat, mouse or human kidney microsomes or postmitochondrial supernatants, several recombinant human cytochrome P450s, prostaglandin H synthase or horseradish peroxidase.

4.1.1.4. Excretion

OTA and its metabolites are excreted with the urine and the faeces. The urinary route appears to predominate in humans and non-human primates, while biliary and faecal excretion appears to be preferred in rats (Dietrich et al., 2005). Both routes are slow, owing to the high binding of OTA to plasma proteins and the low rate of metabolism. Studer-Rohr et al. (2000) reported that about 3% of a single oral dose of tritium-labelled OTA was excreted with the daily urine by a male human during the first 6 days, with a total urinary excretion of 62% of the dose after 75 days. Studies in rats and mice have demonstrated that OTA and some of its metabolites are prone to enterohepatic circulation, and Fuchs and Hult (1992) have proposed that differences in the extent of enterohepatic circulation of OTA might, in part, be responsible for the differences in plasma half-life between the species.

Renal excretion of OTA is of particular interest because the kidney is the major target organ of OTA toxicity. Because of its high plasma protein binding, OTA undergoes tubular secretion rather than glomerular filtration, followed by reabsorption at all segments of the nephron (Ringot et al., 2006). According to Jutabha et al. (2011), the transport of OTA into the proximal tubule cells of human kidneys is mediated by OAT1 and 3 from the basolateral (blood) side and by OAT4 from the apical (proximal tubule) side, whereas multidrug-resistant protein (MRP) 2 and efflux transporter NPT4 mediate the secretion from the proximal tubule cell into the tubule. Because OAT1, 3 and 4 are more efficient than MRP2 and NPT4, high intracellular concentrations of OTA are reached (Jutabha et al., 2011). The reabsorption of secreted and filtered OTA not only leads to its accumulation in the renal tissue but also delays its excretion.

4.1.1.4.1. Transfer/excretion to human milk

Several studies have reported the detection of OTA in human milk, and a correlation between the OTA concentration in milk and the dietary intake has been shown (Skaug et al., 2001). Studies from European countries report levels ranging between 10 and 400 ng OTA/L (Degen et al., 2013). According to the literature, OTA levels are significantly higher in milk of habitual consumers of bread, bakery products, cured pork meat and sweets. In addition to OTA, the occurrence of OTalpha was also monitored in milk and blood from nine lactating women (Muñoz et al., 2010). The concentration levels of unconjugated OTalpha in breast milk were significantly lower than those observed for OTA (40 ± 30 ng/L vs. 106 ± 45 ng/L). However, OTalpha concentrations were almost eight times higher (840 ± 256 ng/L) after an enzymatic treatment of breast milk with β -glucuronidase/sulfatase, while the OTA concentration remained the same. This was an indication of the occurrence of OTalpha conjugates in milk. The lactational transfer of OTA was later reported by the same group by comparing 21 mother–child pairs with parallel collection of maternal blood, milk and of infant urine samples over a period of up to 6 months (Muñoz et al., 2014). OTA was detected in almost all maternal blood plasma samples, at concentrations

ranging between 72 and 639 ng/L. An average milk/plasma (M/P) ratio of 0.25 was reported. The authors observed that a higher fraction of circulating OTA was excreted in colostrum (M/P 0.4) than with mature milk (M/P \leq 0.2). However, the M/P ratios varied substantially between individuals. OTA concentrations in infant urine correlated with OTA levels in concurrently collected milk samples.

4.1.1.5. Summary of toxicokinetics

OTA is a cumulative mycotoxin with relatively rapid absorption and distribution but slow elimination and excretion, which is mostly due to its high extent of binding to plasma proteins in particular albumin and its low rate of metabolism. Both faecal and urinary excretion are important for the plasma clearance of OTA. Plasma half-life range from several days in rodents and pigs to several weeks in humans and non-human primates. The major metabolic pathway of OTA is its hydrolysis to OTalpha, which is particularly pronounced in ruminants, and subsequent glucuronic acid conjugation while oxidative metabolism appears to be of minor importance. Likewise, formation of reactive metabolites capable of covalent binding to DNA, although demonstrated in photochemical and iron-containing systems, appears to be very minor or absent under *in vivo* conditions.

4.1.1.6. Transfer to food of animal origin

In addition to food derived from OTA-contaminated plant products, e.g. coffee, beer and wine, some animal-derived food items may contain significant levels of OTA. Because OTA is frequently present in the feed of food-producing animals and has a high bioavailability and long half-life in some monogastric farm animals such as pigs, preruminant calves and rabbits, OTA may accumulate in the meat and organs of such animals (Battacone et al., 2010; Duarte et al., 2011).

Poultry species appear to eliminate OTA faster than monogastric mammalian species, resulting in a low OTA accumulation in the blood and tissues (Galtier et al., 1981; Schiavone et al., 2008). Likewise, transfer of OTA into eggs appears to occur only when OTA intake is very high. For example, no OTA could be detected in eggs when hens were fed diets containing 0.3 or 1 mg OTA/kg of feed, but OTA was found in eggs of laying hens fed OTA at 10 mg/kg bw (cited in Battacone et al., 2010). Bozzo et al. (2011) did not detect OTA in the eggs of laying hens fed a diet containing 2 mg OTA/kg of feed.

In contrast to monogastric animals, ruminants such as cows, sheep and goats are capable of degrading OTA to the virtually non-toxic OTalpha in their rumen by the microflora (Fink-Gremmels, 2008; Battacone et al., 2010). Hydrolysis of OTA to OTalpha (Figure 2) has also been observed *in vitro* with cow rumen fluid and is attributed to its protozoan fraction (Kiessling et al., 1984). Consequently, only a small amount of intact OTA is absorbed, which explains the comparably high tolerance of cattle to OTA toxicity and the low levels of OTA in bovine tissues (Zhang et al., 2019 and literature cited therein). However, the ability to detoxify OTA is strictly related to a functional rumen and may change when the feed composition is altered, e.g. a high proportion of protein-rich concentrates in feed which may modify the hydrolytic capacity of rumen microorganisms (Fink-Gremmels, 2008; Mobashar et al., 2012). Similar to cattle, small ruminant species such as sheep and goats are protected against the toxicity of OTA by their rumen microorganisms (Battacone et al., 2010).

In accordance with the low level of intact OTA reaching the circulation of ruminants, transfer into cow milk is expected to be very low (Fink-Gremmels, 2008). Indeed, analysis of commercially available milk samples in Italy showed that only 3 out of 83 samples contained OTA at levels between 70 and 110 ng/L, with an LOQ of 5 ng/L (Pattono et al., 2011). Out of 132 French milk samples, only three were found to contain OTA levels above the LOQ of 5 ng/L (Boudra et al., 2007). Galtier (1991) estimated that 0.01% of the OTA in cattle feed would be transferred into cow milk. The very low transfer of OTA from feed into the milk and tissues of cows was confirmed in a recent experiment by Hashimoto et al. (2016). When lactating Holstein cows were fed a diet containing 100 μ g OTA per kg of dry matter for 28 days, no OTA was detected in the milk or in liver, kidney, muscle or fat with an LOQ of 0.1 μ g/kg. For dairy ewes, Boudra et al. (2013) also determined a very low transfer rate (< 0.02%) for OTA from feed into milk.

Although levels of OTA in the milk of ruminants appear to be very low, OTA occurrence may be higher in dairy products such as cheese. Dall'Asta et al. (2008) first reported on the occurrence of OTA in commercial samples of blue-mould ripened cheeses at levels ranging from 0.25 to 3.0 μ g/kg, and provided circumstantial evidence that the OTA does not originate from a contamination of the milk but is formed during ripening and storage of the cheese. More recently, higher levels of OTA were detected in the rind (1–262 μ g/kg) and interior (18–146 μ g/kg) of traditional handmade semi-hard cheeses (Pattono et al., 2013). More information on the occurrence of OTA in cheese is reported in Section 4.7.2.

The toxicokinetics of OTA was previously studied in rainbow trout (Fuchs et al., 1986), carp (Hagelberg et al., 1989) and more recently in Atlantic salmon (Bernhoft et al., 2017). The oral bioavailability of OTA appears to be low and it distributes mainly to liver and kidney. Binding to proteins in blood is low and elimination is rapid. Only trace amounts are transferred to edible tissue, *i.e.* muscle, making fish a negligible source of exposure.

4.1.1.6.1. Summary of transfer to animal-derived food

Because of its long half-life OTA may accumulate in tissues of monogastric farm animals such as pigs and thus be present in meat and meat products. Due to efficient degradation in the rumen OTA levels in the milk and edible tissues of cows and other ruminants are low. In fish, OTA has a short half-life and very low tissue levels.

4.1.2. Biomarkers of exposure

The issue of possible adverse effects observations in humans, including Balkan endemic nephropathy and other endemic nephropathies, is discussed in Section 4.2.6 Observations in humans.

Concerning OTA biomarkers of exposure, MS-based methods have been developed for biological fluids (*i.e.* blood, urine, breast milk) and used extensively for biomonitoring studies. Besides OTA, its major metabolites are detected and (semi)quantified as well.

In the previous EFSA opinion (EFSA, 2006), several, then considered recent, studies on OTA concentrations in human blood, urine and milk were presented and compared with previous findings. In the seven studies presented, mean plasma concentrations of OTA in blood, serum or plasma ranged from 0.17 to 0.56 ng/mL while individual blood concentrations ranged between 0.1 and 10 ng/mL, overall confirming results obtained in previous studies. The CONTAM Panel then concluded that there was a declining trend in OTA plasma levels in recent studies compared to earlier results. It was noted that relating dietary intake to OTA in blood is hampered by its long half-life in plasma due to protein binding and that plasma concentration represents the integrated dietary OTA intake over a longer period of time. Determination of OTA in urine appears to be a more suitable marker for recent exposure as detection methods are more sensitive (about 0.01 ng/mL). Since OTA is excreted in breast milk, analysis of human milk samples could serve as an additional exposure marker (OTA levels detected in breast milk range from 1.2 to 182 ng/L).

Since 2006, a series of new studies on biomarkers of exposure became available.

4.1.2.1. OTA and metabolites in plasma/serum/blood

Coronel et al. (2011) reported OTA levels of 0.50 (median) and 0.06–10.92 ng/mL (range) in 325 inhabitants from Spain and also reviewed earlier studies reporting levels of OTA in serum/plasma and found no new studies since 2006.

Duarte et al. (2010, 2011) reported levels of OTA from Portugal. Values varied slightly between geographical areas and mean values of 0.46–1.01 ng/mL were found in men whereas women had somewhat lower mean values, 0.38–0.60 ng/mL. In Italy, OTA values in serum/plasma in 324 individuals were 0.029–2.9 ng/mL with a mean value of 0.229 ng/mL. Less than 5% of the samples were above 0.5 ng/mL (di Giuseppe et al., 2012). Soto et al. (2016) provided a review of more recent studies covering the period from 2005 to 2015. Median OTA values in serum/plasma varied from 0.15 to 18.0 ng/mL. The higher value being from Tunisian patients with renal failure. In European samples, the median values ranged from 0.15 to 1.098 ng/mL. The LOD of the methods employed varied considerably and the fraction of positive samples varied accordingly.

In more recent studies from Bangladesh and Germany (Ali et al., 2016, 2017, 2018), OTalpha was determined. This metabolite was also to a large extent conjugated and the concentration varied more than OTA. The OTalpha/OTA ratio varied from 0.09 to 2.29 in samples from Bangladesh. There was limited success in correlating serum/plasma values with dietary intake of OTA (Coronel et al., 2010).

Cramer et al. (2015), using dried blood spots, reported the presence of OTA and the modified OTA isomer, 2'R-OTA, that may form upon roasting coffee (see Section 2.1.1). 2'R-OTA was only detected in samples from coffee drinkers, whereas OTA was found at a similar mean concentration (0.21 ng/mL) in both non-coffee drinkers and in coffee drinkers. In the group of coffee drinkers ($n = 34$), the mean and SD concentration was 0.11 ± 0.093 ng/mL with a range of 0.021–0.414 ng/mL. On average, the 2'R-OTA concentrations were about half of that of OTA. In a Swedish study on adolescents (about 3,000 students) from the 5th, 8th and 11th grade (Warensjö Lemming et al., 2015), 2'R-OTA was found in 8.3% of the serum samples, all from the 8th and 11th grade. Average concentrations varied

between 0.028 and 0.037 ng/mL with a maximum of 0.136 ng/mL, and the 2'R-OTA concentrations varied with coffee consumption. OTA was detected in 49–69% of the serum samples from all groups and mean concentration were 0.050–0.059 ng/mL with a maximum of 0.658 ng/mL.

Attempts have been made to estimate OTA intakes from plasma concentrations taking into account the plasma clearance and bioavailability of OTA assuming only glomerular filtration (Coronel et al., 2010). Different values for the plasma clearance have been used resulting in different daily intake estimates of OTA as described by Coronel et al. (2010). Using a plasma clearance of 0.99 mL/kg bw per day and 50% bioavailability, median plasma concentrations between 0.15 and 1.10 ng/mL reported from Europe would correspond to daily intakes of 0.30–2.17 ng/kg bw. With the lower clearance value (0.67 mL/kg bw per day), intake values would be 30% lower. Although being highly uncertain, the estimated intake values were within the same order of magnitude as those obtained in the exposure assessment (see Section 4.8.1).

In summary, although no formal trend analyses have been conducted there seems to be little change in OTA concentrations in serum/plasma/blood reported in studies published since the last EFSA CONTAM opinion on OTA.

4.1.2.2. OTA and metabolites in urine

Sensitive analytical techniques are necessary for determination of the low urinary OTA concentrations. In addition, OTA metabolites which include phase II metabolites of OTA, OTalpha and also OTalpha glucuronides also make up a considerable fraction of OTA and OTA metabolites excreted into urine (Ali et al., 2017; Muñoz et al., 2017). Application of enzymatic hydrolysis of the urine sample prior to MS-analysis is recommended because phase II metabolites may escape direct detection because of lower ionisation. Reported urinary concentrations of OTA and OTalpha with and without prior enzymatic hydrolysis were reviewed by Ali and co-workers (Ali et al., 2017). European populations had a range of mean OTA concentrations without hydrolysis between 0.009 and 0.04 ng/mL. OTalpha was not determined in these studies. Using hydrolysis prior to analysis, the mean values reported varied for OTA from 0.07 to 0.46 ng/mL, while OTalpha had a mean concentration range of 0.44–2.88 ng/mL. In a Swedish study (Mitropoulou et al., 2018), OTA was determined after enzymatic hydrolysis in urine samples from 250 adults and 50 children. There were 51% positive adult and 96% positive child samples. Positive adult samples had a mean and SD concentration of 0.89 ± 0.50 ng/mL, range 0.12–2.76 ng/mL. Adjusting for density (1.015) gave the following figures for adults: 1.20 ± 1.68 mg/mL, range 0.09–16.5 mg/mL. Corresponding values for children were, unadjusted: 0.18 ± 0.15 ng/mL, range 0.05–0.93 ng/mL. Density (1.019) adjusted figures were 0.13 ± 0.08 mg/mL, range 0.06–0.52 ng/mL. The rate of positive samples was within a large range of 12.5–100% positive samples in other studies, but the mean crude total OTA concentration (0.89 ± 0.50 ng/mL, range 0.12–2.76 ng/mL) was about three times higher than other European studies indicating a higher exposure.

Recently, Sueck et al. (2019) identified a new metabolite of OTA in urine i.e. ochratoxin-N-acetyl-L-cystein (OTB-NAC) derived from a glutathione conjugation reaction of OTA. The metabolite was detected in 11 of 18 urine samples and could be quantified in five ranging from 0.023 to 0.176 ng/mg creatinine.

Attempts have been made to estimate daily intake of OTA based on urinary concentrations in spot samples, but the results are considered questionable because of long half-life and strong plasma protein binding and uncertain excretion rates (values from 2.6% to 50% have been used) (Solfrizzo et al., 2014; Degen, 2016; Mitropoulou et al., 2018).

4.1.2.3. OTA in breast milk

There are only few studies on the transfer of OTA from plasma to breast milk in humans (see Warth et al., 2016). Muñoz et al. (2014) reported a study from Chile in 21 mother–children pairs that were followed for up to 6 months. The authors reported, overall, an average level in breast milk from this cohort of 52 ± 46 ng/L. The milk to plasma ratio varied considerably changing from the first days with colostrum (0.40 ± 0.26) to later stages (0.15 ± 0.26 after 15–30 days, 0.09 ± 0.06 after 2 months and 0.26 ± 0.19 after 4 months). Breast milk mean concentrations were 86 ± 59 ng/L in the first week, 33 ± 27 after 15–30 days, 27 ± 19 ng/L after 2 months, 30 ± 14 ng/L after 4 months. No sample was collected at 6 months. Corresponding OTA mean concentrations in infant urine were 156 ± 36 ng/L in the first week, 36 ± 37 ng/L after 15–30 days, 51 ± 38 ng/L after 2 months, 36 ± 23 ng/L after 4 months and 47 ± 7 ng/L after 6 months.

Dietary exposures to OTA are reflected in OTA levels in plasma/serum, blood, urine and breast milk. Overall, in Europe, these levels have not changed since the last EFSA evaluation.

4.2. Toxicity

4.2.1. Acute toxicity

In the EFSA opinion of 2006, acute toxicity of OTA was not discussed and an acute reference dose (ARfD) was not established.

JECFA (FAO/WHO, 1991) reported LD₅₀ values for OTA in various species based on literature compilations by Harwig et al. (1983). Oral LD₅₀ values ranged from 46 to 58.3 mg/kg bw in mouse and 20–30.3 mg/kg bw in rat. LD₅₀ values in rat neonate, dog, pig and chicken were 3.9, 0.2, 1 and 3.3 mg/kg bw, respectively. In a study with male rats given a single doses (gavage) of 0, 17 or 22 mg OTA/kg bw, respectively, earliest changes identified were multifocal haemorrhages and fibrin thrombi in different organs. Other changes were hepatic and lymphoid necrosis, villous atrophy in particular in the jejunum and nephrosis (Albassam et al., 1987). In subsequent JECFA evaluations (FAO/WHO, 1996, 2001, 2008), no further data on acute toxicity on OTA were presented (and no ARfD was derived). An ARfD was not established in any of their evaluations.

The CONTAM Panel did not identify new studies (published after the EFSA opinion of 2006) relevant for the assessment of acute toxicity of OTA.

4.2.2. Repeated dose studies

4.2.2.1. Introduction

The repeated dose toxicity of OTA has been previously reviewed by EFSA (EFSA, 2006). Experimental data identified the kidney as the main target organ for the adverse effects of OTA. Immunotoxic, neurotoxic and teratogenic effects were observed at high dose levels. OTA has been shown to induce dose- and time-dependent nephrotoxicity in all mammalian species tested, including mice, rats, dogs and pigs, with marked differences in sensitivity to OTA toxicity between sex and species. Long-term administration of OTA causes renal tumours in rats and mice. Rats are more sensitive to renal tumours formation by OTA than mice, and higher incidences of renal tumours are observed in male animals as compared to females. Renal tumours produced by OTA in rats are preceded by evidence of renal toxicity as shown in short-term toxicity studies. The effects of OTA on the kidneys in rats and pigs were identified as the most sensitive and pivotal endpoints of OTA. In a 2-year gavage study with Fischer 344/N rats (NTP, 1989), the NOAEL and LOAEL for OTA-induced nephrotoxicity were 21 and 70 µg OTA/kg bw per day when dosed 5 days per week, respectively, equivalent to 15 and 50 µg/kg bw per day. In a 90-day study in Wistar rats, mild and reversible renal changes were reported at a dose of 200 µg OTA/kg diet (Munro et al., 1974), equivalent to 15 µg OTA/kg bw per day (FAO/WHO, 2001). On the basis of a series of studies in female pigs, an LO(A)EL for minimal effects on the kidney (minimal morphological changes, renal enzymes and renal function tests) was identified by EFSA (and previously by JECFA) at 8 µg/kg bw per day from a 90-day feeding study (FAO/WHO, 1991, 1996, 2001, 2008; EFSA, 2006). EFSA concluded that '8 µg OTA/kg bw. per day is a LOAEL that represents an early marker of renal toxicity in experimental animals (i.e. female pigs) and likely to be close to a NOAEL, as the observed changes in biochemical parameters indicate transient changes in the kidneys' (EFSA, 2006). The CONTAM Panel re-evaluated the pivotal studies in rats and pigs used as a basis to establish a HBGV in the previous EFSA opinion (EFSA, 2006). In addition, new *in vivo* toxicity studies with mice, rats, rabbits and pigs published since the 2006 opinion of EFSA was reviewed to identify possible new evidence relevant for the hazard identification and characterisation of OTA.

4.2.2.2. Repeated dose studies in rats considered in the previous EFSA assessment

Details of the pivotal repeated dose toxicity studies in rats published before 2006 are summarised in Appendix C. On the basis of these studies, an LOAEL for minimal renal changes at 15 µg OTA/kg bw was derived from a 90-day feeding study in Wistar rats (Munro et al., 1974).

4.2.2.3. Repeated dose studies in rats published since 2006

Most of the studies in rats conducted since 2006 were designed to elucidate the mechanism of OTA-induced nephrotoxicity and thus employed dose levels known to be toxic. In some studies, hepatotoxic or immunotoxic effects of OTA were investigated. Table 1 provides a description of new subacute and subchronic toxicity studies in rats. None of the studies described in Table 1 (and briefly

summarised in the text below) provided NOAELs/LOAELs lower than the LOAEL of 15 µg/kg bw derived from the 90-day feeding study in Wistar rats from Munro et al. (1974).

Subacute and subchronic studies were conducted in male F344/N rats and F344 gpt delta rats employing dosing regimens similar to the 2-year gavage study in F344/N rats (NTP, 1989). Essentially, these confirmed renal changes at a dose of 50 µg/kg bw per day observed previously in this rat strain (Rached et al., 2007, 2008; Adler et al., 2009; Sieber et al., 2009; Hoffmann et al., 2010; Dai et al., 2014; Guo et al., 2014; Kuroda et al., 2014; Qi et al., 2014a,b; Zhu et al., 2016a). Consistent with the NOAEL of 15 µg/kg bw per day derived from the NTP study (NTP, 1989), no effects on renal histology, urinary biomarkers indicative of kidney injury, and expression of kidney injury marker genes or genes mechanistically linked to OTA toxicity were observed after exposure of male F344/N rats to 15 µg/kg bw per day for up to 90 days (Rached et al., 2007, 2008; Adler et al., 2009; Sieber et al., 2009; Hoffmann et al., 2010).

Table 1: Repeated dose studies in rats published after 2006

Strain	Dose and animals per group	Duration/ time of observation	Main effects observed	Effect level	Reference

4.2.2.4. Repeated dose studies in mice published since 2006

New repeated dose toxicity studies in mice published since the 2006 EFSA opinion is described in Table 2. Consistent with the lower sensitivity of mice to OTA toxicity as compared with rats and pigs, none of the new studies provided NOAELs/LOAELs that were lower than the LOAELs of 15 and 8 µg/kg bw previously established in rats and pigs, respectively (FAO/WHO, 2001; EFSA, 2006).

4.2.2.5. Repeated dose studies in rabbits published since 2006

Table 3 provides a description of subacute and subchronic studies in rabbits published since 2006. Clinical signs of toxicity, renal histopathological changes and biochemical changes indicative of liver and kidney toxicity were reported in rabbits given OTA in diet corresponding to approximately 30 µg/kg bw per day for up to 2 months. Thus, studies in rabbits did not provide more sensitive endpoints of OTA toxicity compared to the LOAELs of 15 and 8 µg/kg bw previously established in rats and pigs, respectively (FAO/WHO, 2001; EFSA, 2006).

Table 2: Repeated dose studies in mice published after 2006

4.2.2.6. Repeated dose studies in pigs considered in the previous EFSA assessment

In previous assessments, nephrotoxicity of OTA in pigs was identified as the most sensitive endpoint of OTA toxicity, and an LOAEL of 8 µg/kg bw derived from a series of studies in pigs was used to establish a HBGV (FAO/WHO, 1991, 1996, 2001, 2008; EFSA, 2006). From these studies (for details see Appendix C, Table C.2), the CONTAM Panel identified the study of Krogh et al. (1974) selected as the pivotal 90-day study in the previous EFSA opinion and is therefore described in further detail below.

In this study (Krogh et al., 1974), female pigs (Danish Landrace) were given doses (via feed) of 0 (control group), 8, 40 and 160 µg/kg bw per day for 3–4 months (i.e. from 20 to 90 kg bw). Increased water consumption and increased concentrations of creatinine and urea were observed in animals administered OTA at 160 µg/kg bw per day. Increased glucose was detected in urine of pigs given the two highest dose levels (40 and 160 µg/kg bw per day). The average renal clearance of inulin C_{Inulin} and p-aminohippuric acid (PAH) measured after 3–3.5 months was significantly reduced at the highest dose. The average maximal tubular excretion of PAH (T_{mPAH}) and $T_{\text{mPAH}}/C_{\text{Inulin}}$ was reduced in a dose-related manner, with significant changes at all doses. In contrast, reabsorption of glucose and the ability to concentrate urine (as assessed by urine specific gravity and osmolality) were only affected at the two highest dose levels (40 and 160 µg/kg bw per day). Alterations in the enzymatic activities of glutamate dehydrogenase (GLDH), leucine aminopeptidase (LAP) in renal cortex were also recorded at the two highest dose levels. However, microscopic kidney lesions were observed even at the lowest dose. At this dose, these changes were confined to the proximal tubules and consisted of tubule dilation with reduced brush boarder, pycnotic nuclei, mitotic figures, desquamation of tubule cells and a slight increase of interstitial fibrous tissue. The microscopic kidney lesions in the higher dose groups included degenerative changes of the proximal tubule epithelium, dilation of cortical tubules, tubular atrophy, thickened basement membrane, glomerulosclerosis and interstitial fibrosis. The frequency of animals with kidney lesions at the end of the exposure period in the control, 8, 40 and 160 µg/kg bw per day group was 0/9, 4/9, 9/9 and 4/4, respectively.

While the previous evaluation in 2006, used dose-related reduction in T_{mPAH} and $T_{\text{mPAH}}/C_{\text{Inulin}}$ which occurred in parallel with microscopic lesions, as the critical effect and identified the same LOAEL of 8 µg/kg bw, it is now well established that renal transport of OTA is mediated by OATs. Therefore, it was concluded that reduced tubular excretion of PAH (a prototype OAT substrate), which was previously interpreted as evidence of impaired renal function by OTA, is likely also to be due to interference by OAT-mediated transport and cannot be considered as adverse.

However, based on evidence of microscopic kidney lesions, the CONTAM Panel confirmed 8 µg/kg bw as the LOAEL for nephrotoxicity in this study.

4.2.2.7. Repeated dose studies in pigs published since 2006

The repeated dose studies in pigs published since 2006 are described in Table 4 below. A series of studies published after 2006 investigated the effects of OTA in female cross-bred weaned piglets (TOPIGS-40) exposed to OTA via feed at the recommended EU guidance value of 50 µg OTA/kg diet¹¹ (corresponding to approximately 2.7 µg/kg bw based on reported body weights and feed intakes) for 33 days (Marin et al., 2016, 2017a,b, 2018). Exposure to OTA had no effect on growth performance or organ weights. Biochemical analysis of plasma revealed a small but statistically significant decrease in total protein and albumin, accompanied by a significant increase in alanine aminotransferase and triglycerides. The activity of superoxide dismutase (SOD) was reported to be significantly increased in animals given OTA as compared to controls. The biochemical changes were interpreted by the authors of the study as an indication of hepatocellular injury (Marin et al., 2016, 2017a,b). Histopathological evaluation of liver tissue to confirm hepatotoxic effects was not performed. There was no evidence of kidney injury. However, genome-wide expression profiling revealed significant alterations in 105 different renal transcripts related to immune response, oxidative stress response, cell growth and cell death (Marin et al., 2017a). Changes in parameters indicative of altered immune and oxidative stress response were also reported to occur in the gut (Marin et al., 2017b). The authors of these studies emphasised the need to perform confirmatory in vivo studies on larger number of animals to provide a reliable database for regulatory purposes (Marin et al., 2016). In a subsequent study from the same group, 15 cross-bred TOPIG hybrid [(Landrace × Large white) × (Duroc × Pietrain)] pigs (n = 5) were

¹¹ Commission Recommendation of 17 August 2006 on the presence of deoxynivalenol, zearalenone, ochratoxin A, T-2 and HT-2 and fumonisins in products intended for animal feeding. OJ L 229, 23.8.2006, p. 7–9.

exposed to a diet contaminated with 250 µg OTA/kg feed (corresponding to a dose of 12.5 µg OTA/kg bw per day) for 28 days (Marin et al., 2018). In contrast to the decrease in total protein and albumin reported in Marin et al. (2016), exposure to OTA resulted in a significant increase in the serum concentration of total protein, albumin, triglycerides and creatinine accompanied by a decreased total antioxidant capacity in liver and kidney (Marin et al., 2018).

Indications for cellular stress and inflammatory response (increased TNF- α and IL-10 in plasma, decreased HO-1 in kidney) were reported in 43-day study in weaned pigs (Large-White, castrated male) fed on a diet containing 181 ± 34 µg OTA /kg feed (corresponding to 9 µg/kg bw per day, calculated based on body weight and food consumption data provided in the paper) (Bernardini et al., 2014).

Treatment of weaned piglets (Hungarian Large White \times Hungarian Landrace F1, sex ratio: 1:1) with experimental diets contaminated with OTA at levels corresponding to an intake of approximately 12 µg/kg bw per day for 42 days resulted in reduced feed consumption and daily weight gain and indications of oxidative stress (increased malondialdehyde in liver, decreased glutathione peroxidase activity in liver and kidney) (Balogh et al., 2007).

In male pigs (Zegers hybrid), 30-day treatment with OTA was reported to cause an increase in serum creatinine and urea and a decrease in serum glucose and total protein on days 10, 20 and 30 (Pleadin et al., 2012). Histopathological evaluation of tissues was not conducted. The CONTAM Panel noted the unclear reporting of the route of administration (OTA in feed vs. OTA administered via gelatine capsule into mouth of pigs) and the apparent lack of time-matched controls. Based on default values (WHO/IPCS, 2009; EFSA FEEDAP Panel, 2012; EFSA Scientific Committee, 2012a), the CONTAM Panel calculated an approximate daily intake of OTA of 9 µg/kg bw.

In a series of experiments in cross-bred ([Landrace \times Yorkshire] \times Duroc) piglets administered OTA at 0, 400, 800 µg/kg diet (corresponding to approx. 20 and 36 µg/kg bw per day) for 42 days, decreased growth performance and renal histopathological changes were observed. These consisted of hyperchromatic nuclei and cytoplasm, nuclear atrophy, necrosis and exfoliation of proximal tubule cells and were consistently reported at doses equal or greater than 400 µg OTA/kg diet (Zhang et al., 2016; Gan et al., 2017b). Treatment with OTA at these dose levels also lead to a dose-related decrease in TCR-induced T lymphocyte viability in peripheral blood lymphocytes and splenocytes, accompanied by decreased concentrations of IL-2 and increased concentrations of TNF- α in serum. Increased GRP78 expression, increased p38 and ERK1/2 phosphorylation and increased expression of the autophagy-related gene *Atg5* and *LC3II* genes were observed in kidney and spleen of OTA-treated pigs (Gan et al., 2017b), suggesting to the authors that nephrotoxicity and immunotoxicity of OTA may involve ER stress, activation of MAPK signalling and autophagy (Gan et al., 2017b,c).

Proximal tubule injury accompanied by increased serum creatinine and urea was reported in male and female pigs (Landrace \times Bulgarian White) fed a mouldy diet containing 500 µg OTA/kg feed (corresponding to approximately 15 µg/kg bw per day) for 3 months (Stoev et al., 2012). Slight degenerative changes were also recorded in the duodenal or jejunal mucosa. At the same dose, a strong decrease in antibody titre was observed after immunisation against Morbus Aujeszky (Pseudorabies), suggesting that OTA affects humoral immune response (Stoev et al., 2012).

4.2.2.7.1. Summary remarks on studies in pigs published since 2006

Overall, the CONTAM Panel concluded that, the new studies in pigs, even though most of them are of shorter duration, support OTA-mediated effects at dose levels close to the previously established LOAEL of 8 µg/kg bw per day but did not provide LOAELs that were below this dose. The CONTAM Panel noted that the subtle changes in biochemical parameters reported in the 33-day feeding study using only one dose by Marin et al. (2016) could not be considered as being clearly adverse and are inconsistent with a subsequent report from the same group (Marin et al., 2018). Therefore, the CONTAM Panel considered that the study by Marin et al. (2016) was not suitable for hazard characterisation.

ALT: alanine aminotransferase; AST: aspartate aminotransferase; LOAEL: lowest observed adverse effect level; NOAEL; no observed adverse effect level; n: number; PCT: proximal convoluted tubular; GPx: Glutathione peroxidase; TCR: T-cell receptor.

*: NOAEL/LOAEL not explicitly reported but derived from data presented in study.

** : Calculated using parameters (bw, feed intake) provided in the paper.

***: Calculated using default values provided in EFSA Scientific Committee (2012a), EFSA FEEDAP Panel (2012), WHO/IPCS (2009).

(1): The experimental diet also contained low levels of fumonisin B₁ (88 µg/kg corresponding to approx. 5 µg/kg bw per day), which is below the NOAEL for fumonisins in pigs.

(2): Unclear reporting of route of administration: 'The experimental group was treated with feed contaminated with 300 µg OTA/kg (300 ppb). OTA as a pure chemical (standard) was mixed with lactose and distributed in gelatin capsules that were applied directly into pig mouth.'

4.2.3. Chronic toxicity and carcinogenicity studies

4.2.3.1. Studies with rodents published before 2006

OTA has been shown to cause increased incidences of renal tumours in rats and mice, with male rats being most sensitive, and liver tumours in mice (both sexes). Since it has been considered as a pivotal study for characterisation of carcinogenic hazards by OTA in several previous assessments (FAO/WHO, 1991, 1996, 2001, 2008; EFSA, 2006), the 2-year gavage study with from NTP (1989) is described here again in detail. Groups of male and female F344/N rats ($n = 80/\text{group}$) were administered doses of 0, 21, 70 and 210 $\mu\text{g}/\text{kg}$ bw OTA (98% pure) in corn oil by gavage 5 days per week for up to 2 years (equivalent to 0, 15, 50 and 150 μg OTA/kg bw per day), with interim sacrifices at 9 and 15 months ($n = 15/\text{group}$ per sex) (NTP, 1989). After 9 and 15 months, increased incidences of renal tubular cell neoplasms were observed in males along with non-neoplastic kidney lesions characterised by hyperplasia, degeneration and karyomegaly of renal tubular epithelial cells in both males and females. At both time points, renal tubular epithelial karyomegalic changes were evident in 100% of male and female rats in the 50 and 150 $\mu\text{g}/\text{kg}$ bw dose group, whereas no such changes were recorded in rats given the lower dose of 15 $\mu\text{g}/\text{kg}$ bw. After 2 years, increased incidences of kidney tubule adenoma and carcinoma accompanied by proliferative and degenerative kidney lesions (degeneration, hyperplasia, karyomegaly, proliferation) were observed in the 50 and 150 $\mu\text{g}/\text{kg}$ dose group of both sexes, with highest incidences in males (Table 5).

Table 5: Incidence of renal tumours and karyomegaly in male F344/N rats (NTP, 1989)

Dose in $\mu\text{g}/\text{kg}$ bw per day	Adenomas	Carcinomas	Adenomas and carcinomas	Karyomegaly
0	1/50 (2%)	0/50 (0%)	1/50 (2%)	0/50 (0%)
15	1/50 (2%)	0/50 (0%)	1/50 (2%)	1/50 (2%)
50	6/51 (12%)	16/50 (31%)	20/51 (39%)	51/51 (100%)
150	10/50 (20%)	30/50 (60%)	36/50 (78%)	50/50 (100%)

Compared with rats, mice appear to be less susceptible to renal carcinogenicity of OTA. In a 24-month feeding study in C57BL/6J X C3H)F1 (B6C3F1) mice, renal adenomas (26/49) and carcinomas (14/49) were observed in male mice fed diet containing 40 mg/kg OTA (the crude preparation contained 84% OTA, 7% OTB and 9% benzene) (Bendele et al., 1985), corresponding to approximately 4.5 mg/kg bw per day (Huff, 1991). No renal neoplasms were found in female B6C3F1 mice and in males fed OTA at 1 mg/kg in diet, whereas the incidence of hepatocellular adenomas and carcinomas was slightly increased in male and female B6C3F1 mice administered OTA-contaminated diet (Bendele et al., 1985). Renal cystadenomas and renal cell tumours as well as liver tumours were also recorded in male ddY and DDD mice exposed to OTA via feed (Kanisawa and Suzuki, 1978; Huff, 1991), although the number of animals per group was considered insufficient to derive adequate information on tumour incidence (Bendele et al., 1985).

4.2.3.2. Studies with rodents published after 2006

New studies investigating the carcinogenic effects of OTA in rodents (Table 6) are briefly summarised below.

In a group of 34 male F344 rats administered OTA in diet corresponding to 50 μg OTA/kg bw per day for up to 105 weeks, two renal adenomas and four renal carcinomas corresponding to a renal carcinoma incidence of 12% were observed (Mantle and Kulinskaya, 2010). The same group reported a renal carcinoma incidence of 20% following chronic dietary administration of OTA to male F344 rats at approximately 250 μg OTA/kg bw per day. In this study, male F344 rats were given OTA via feed at a dose corresponding to 300 μg OTA/kg bw until rats reached a body weight of 333 g, and were then maintained at a dose of 100 $\mu\text{g}/\text{rat}$ (Mantle et al., 2005). No details such as initial number of animals per dose group or number of controls were presented. Leukaemia occurred in 50% of animals. A total number of 64 OTA-treated rats were used as a basis to establish renal tumour incidence. In these animals, a total of 16 renal tumours were discovered after ≥ 75 weeks of OTA treatment (i.e. total renal tumour incidence 25%). Most tumours were unilateral carcinomas, while renal tumours in three animals were classified as adenomas (i.e. renal carcinoma incidence 20%). The lower tumour incidences in these feeding studies as compared to the 2-year oral gavage study (NTP, 1989) were considered by the authors to be due to the different routes of administration, i.e. feed vs. gavage, with the lower potency of OTA administered via feed being more relevant to humans (Mantle et al., 2005; Mantle and Kulinskaya, 2010). Considering the high incidence of

mononuclear leukaemia in both controls (69%) and rats dosed with OTA (47% and 50% in animals given OTA at 50 and 250 µg/kg bw per day) that resulted in premature death of animals these studies (Mantle and Kulinskaya, 2010), a pilot study was conducted in hybrid rats (offspring of female Sprague Dawley crossed with male F344) to minimise the confounding factor of spontaneous leukaemia during ageing. Rats (10 males, 3 females) were administered feed contaminated with OTA (5 mg/kg) for 36 weeks, which was estimated to correspond to a dose of ~ 150 µg OTA/kg bw in males and ~200 µg OTA/kg bw in females (Mantle et al., 2010a). A subgroup of animals (5 males, 3 females) was then given sodium barbitate in drinking water for life to test if renal tumour formation could be accelerated by the tumour promoter. Three female rats were used as controls. Renal tumours were found in 2/5 (40%) male rats given OTA, and in 3/5 (60%) male rats given OTA followed by sodium barbitate in drinking water. A small renal tumour (adenoma) was found in a female rat given OTA followed by sodium barbitate. All three females in this group developed mammary tumours. In the control group, a mammary tumour was observed. Barbitate treatment was considered to only slightly accelerate the development of OTA-induced renal tumours (Mantle et al., 2010a). Renal tumours were also observed in male Dark Agouti rats given OTA in diet at 5 µg/kg for 6 and 9 months and monitored throughout natural life, whereas no renal tumours were found in a group of rats administered OTA at 400 µg/kg in the diet for up to 2 years (Mantle, 2009). Based on these findings, the authors suggested OTA at 400 µg/kg in diet (corresponding to ~ 20–30 µg OTA/kg bw) as a threshold dose for OTA-induced renal carcinogenicity in this rat strain (Mantle, 2009).

In a further study in male F344 rats (n = 5; 10 weeks old at beginning of OTA exposure) by the same group, 10-month exposure to OTA at 5 mg/kg diet corresponding to an intake of 300 µg OTA/kg bw per day within the first year of life followed by an exposure-free period for life was reported to cause a 100% incidence of renal carcinomas. In the same study, seven renal carcinomas were found in 12 animals continuously exposed to OTA at the same dose for life, corresponding to a renal carcinoma incidence of 58% (Mantle, 2016). The lower tumour incidence in the continuous exposure may be related to the high incidence of mononuclear leukaemia (41%) and reduced longevity as compared to the 10-month exposure group (75% of rats in the continuous exposure group had already deceased before tumours were discovered in the 10-month exposure group). High incidences of mononuclear leukaemia (69%), but no renal tumours were found in controls.

No renal tumours were observed in p53 heterozygous (p53+/-) and p53 homozygous (p53+/+) mice after chronic exposure to OTA in diet for 26 weeks. In this study, the levels of OTA in diet were adjusted from 1, 15 and 40 mg OTA/kg diet to 0.5, 2 and 10 mg OTA/kg diet (equivalent to ~ 0.03, 0.2 and 1.5 mg OTA/kg bw) due to a rapid weight loss during the first 2 weeks of exposure. Minimal nuclear variability in size (anisokaryosis) was recorded at the low dose of 0.5 mg OTA/kg diet, whereas apoptosis, karyomegaly and tubular degeneration were only at 2 and 10 mg OTA/kg diet. Based on these findings, the authors derived an LOEL (note that the CONTAM Panel considers this to be a LOAEL) for renal changes in p53+/- and p53+/+ mice of 2 mg/kg diet (corresponding to 200 µg/kg bw per day) (Bondy et al., 2015).

In a two-stage mouse skin tumorigenesis protocol, a single topical application of OTA (80 µg/mouse) followed by twice weekly application of 12-O-tetradecanoylphorbol-13-acetate (TPA) for 24 weeks lead to the development of skin tumours in 40% of the animals. These data indicate that OTA has skin tumour initiating properties. Early events induced by single OTA skin application included increased levels of DNA damage (SSBs and γH2AX), induction of the DNA damage response (p53 and p21) and of several markers of oxidative stress (see also section 4.3 on Mode of action) (Kumar et al., 2012). In a follow-up study by the same group, a single topical application of 7,12-dimethyl benz[α]anthracene (DMBA) as tumour initiator followed by twice weekly application for 24 weeks of OTA (20 µg/mouse) as tumour promoter resulted in the development of skin papillomas. Tumours developed in 100% and 40% of mice in DMBA/TPA- and in DMBA/OTA-treated groups, respectively, indicating that OTA is a weak tumour promoter in comparison to TPA (Kumar et al., 2013).

4.2.3.2.1. Summary on toxicity

The CONTAM Panel noted the inadequate study design and unclear reporting of the new studies (published after 2006) investigating the carcinogenic effects of OTA and considered that these provided only limited additional information on OTA carcinogenicity that could serve as a basis for quantitative risk assessment (Table 6). Long-term OTA administration of OTA to female Wistar rats was reported to cause toxic effects on the endocrine pancreas, suggesting diabetogenic potential of OTA (Mor et al., 2017). These effects were evident at a dose higher than those required for nephrotoxicity and renal tumour formation (Table 6), and therefore did not provide a more sensitive endpoint of toxicity.

Table 6: Summary of chronic toxicity studies, including carcinogenicity studies published since 2006

Species	Dose and animals per group	Duration/time of observation	Main effects observed	Effect level	Reference
Chronic toxicity studies in rats					
F344 (♂)	0, 70, 210 µg/kg bw (gavage, corn oil, 5 days/week) equivalent to 0, 50, 150 µg/kg bw per day n = 6	2, 4, 13, 26 weeks	<ul style="list-style-type: none"> Decreased kidney weight (2 weeks: 70 µg/kg bw; 13 weeks: 70, 210 µg/kg bw; 26 weeks: 210 µg/kg bw) Renal histopathological changes involving proximal tubular epithelial cells in OSOM: cytoplasmic vacuolisation and karyomegaly (13 weeks and 26 weeks: 70 and 210 µg/kg bw) 	LOAEL* 50 µg/kg bw per day (based on renal histopathology)	Dai et al. (2014)
F344 (♀)	0, 3 mg/kg diet (corresponding to approx. 300 µg/kg bw per day**), n = 7	6, 9 and 24 weeks	<ul style="list-style-type: none"> Decrease in insulin levels, and increased levels of blood glucagon and glucose Slight to moderate degeneration in Langerhans islet cells Decreased insulin and increased glucagon expression 	300 µg/kg bw per day**)	Mor et al. (2017)
Carcinogenicity studies in rats					
F344 (♂)	0, ~ 1 mg/kg feed corresponding to ~ 50 µg/kg/bw per day' n = 34 (treatment), n = 15 (controls)	Up to 2 years (105-week exposure)	<ul style="list-style-type: none"> Mononuclear leukaemia as the principal morbidity factor (in 47% of the treated group compared with 69% in controls) Renal carcinoma incidence 4/34 (12%), adjusted 34.5% (incidence in controls not provided) 	~ 50 µg/kg bw per day	Mantle and Kulinskaya (2010)
F344 (♂)	~ 250 µg/kg bw per day ⁽¹⁾ No information on controls and total number of animals provided	Up to 2 years (interim sacrifices at 7, 21 days 4, 7, 12 months; n = 4/ dose/time point)	<ul style="list-style-type: none"> Renal carcinoma incidence: 20% (incidence in controls not provided) Tissue-specific transcriptional response in kidney: (7, 21 days; 4, 7, 12 months): markers of kidney injury and cell regeneration, genes regulated by the transcription factors HNF4α and Nrf2 Increased phosphorylation of atypical-PKC (21 d, 12 months) Activation of the MAPK extracellular regulated kinases isoforms 1 and 2 (ERK1/2) and of their substrates ELK1/2 and p90RSK (7, 21 days) 	~ 250 µg/kg bw per day ⁽¹⁾	Mantle et al. (2005) Marin-Kuan (2006) Marin-Kuan et al. (2007)

Species	Dose and animals per group	Duration/time of observation	Main effects observed	Effect level	Reference
Sprague-Dawley ♀ × F344 ♂	0, 5 mg/kg diet (5 µg/kg) for 36 weeks (corresponding to ~ 150 µg/kg bw per day (♂) and ~200 µg/kg bw per day (♀)) followed by sodium barbitate (500 µg/kg in drinking water) for life, n = 5 ♂ (OTA); n = 5 ♂ + 3 ♀ (OTA + barbitate); n = 3 ♀ (controls)	36-week exposure to OTA followed by sodium barbitate (500 µg/kg in drinking water) for life	<ul style="list-style-type: none"> Renal tumours (adenoma + carcinoma): OTA: 2/5 (40%) ♂; OTA + barbitate: 3/5 (60%) ♂, 1/3 (33%) ♀ Mammary tumours: OTA + barbitate: 3/3 (100%) ♀; controls: 1/3 (33%) ♀ 	~ 150 µg/kg bw per day (based on renal tumours)	Mantle et al. (2010a)
Dark Agouti (♂)	5 mg/kg diet (5 µg/kg) (640–250 µg/kg bw per day) the dose falling as animals gained weight, n = 20 (treatment) No controls	3, 6, 9 months exposure (observation throughout natural life)	<ul style="list-style-type: none"> Renal carcinoma: 3 months: 0/20 (0%); 6 months 1/20 (5%); 9 months 4/20 (20%) 	~ 640–250 µg/kg bw per day (based on renal tumours)	Mantle (2009)
	400 µg/kg diet (corresponding to ~20–30 µg/kg bw per day) n = 20 (treatment) No controls	up to 2 years	<ul style="list-style-type: none"> No renal tumours observed 	NOAEL* ~ 20–30 µg/kg bw per day (based on renal tumours)	Mantle (2009)
F344 (♂)	0, 5 mg/kg diet (300 µg/kg bw per day) n = 5 (treatment, 1st year of life) n = 12 (treatment, lifetime exposure) n = 13 (controls)	10-month exposure in 1st year of life vs. lifetime exposure	<ul style="list-style-type: none"> High incidences of mononuclear leukaemia in controls and OTA-treated animals Renal carcinoma: 1st year of life exposure: 5/5 (100%); lifetime exposure 7/12 rats (58%); controls: 0/13 (0%) 	5 mg/kg diet (~ 300 µg/kg bw per day) (based on renal tumours)	Mantle (2016)
Chronic toxicity and carcinogenicity studies in mice					
Swiss albino mice (females)	A single topical application of DMBA (30 µg/mice) or OTA (80 µg/mice) followed by twice weekly application of TPA (2.5 mg) after a week of initiation	24 weeks	<ul style="list-style-type: none"> First incidence of tumorigenesis: DMBA/TPA-treated group: 7th week, OTA/TPA-treated group: 14th week. Skin tumours developed in: DMBA/TPA-treated group: 100% of mice in 15th week; OTA/TPA-treated group: 40% of mice in 18th week 	LOAEL as initiator: OTA (20 µg/mice)	Kumar et al. (2012)

Species	Dose and animals per group	Duration/time of observation	Main effects observed	Effect level	Reference
Swiss albino mice (females)	Single topical application of DMBA (24 µg/mouse) followed by twice weekly application of TPA (2.4 µg/mouse) or OTA (20 µg/mouse) after a week of initiation; n = 10	24 weeks	<ul style="list-style-type: none"> First incidence of tumorigenesis: DMBA/TPA-treated group: 7th week, DMBA/OTA-treated group: 12th week. Skin tumours developed in: DMBA/TPA-treated group: 100% of mice in 15th week; DMBA/OTA-treated group: 40% of mice in 21st week 	LOAEL as promoter: OTA (20 µg/mouse) NOAEL: OTA (10 µg/mice)	Kumar et al. (2013)
P53N5-T (p53+/-) and P53N5-W (p53+/+) mice (♂)	0, 0.5, 2 or 10 mg/kg diet ⁽²⁾ (corresponding to ~ 0, 30, 200, 1,500 µg/kg bw per day) n = 10	26 weeks	<ul style="list-style-type: none"> Reduced relative liver and kidney weight, increased weight of spleen (≥ 2 mg/kg diet) Renal histopathological changes: apoptosis, karyomegaly and tubular degeneration in proximal tubules (2, 10 mg/kg diet, both stains); anisokaryosis (0.5, 2, 10 mg/kg diet, both strains), No kidney tumours Increased incidence and severity of focal hepatocellular necrosis (2, 10 mg/kg diet), no tumours or pre-neoplastic lesions in liver 	LOAEL ⁽³⁾ 200 µg OTA/kg bw per day (based on non-neoplastic kidney lesions)	Bondy et al. (2015)

DMBA: 7,12-dimethyl benz[α]anthracene; ELK1/2 : nuclear substrate ETS protein 1/2; ERK1/2: extracellular signal-regulated kinase 1/2; HNF4 α : hepatocyte nuclear factor 4 alpha; LOAEL: lowest observed adverse effect level; MAPK: mitogen-activated protein kinase; NOAEL: no observed adverse effect level; Nrf2: nuclear factor-erythroid2-related factor 2; OSOM: outer stripe of the outer medulla; OTA: ochratoxin A; p90RSK; ribosomal-S6 kinase; PKC: protein kinase C; TPA: 12-O- tetradecanoylphorbol-13-acetate.

*: NOAEL/LOAEL not explicitly reported but derived from data presented in study.

(1): 'As from their initial weight of ~ 175 g, daily dietary intake was 300 µg OTA/kg bw, but was held at 100 µg/rat after animals reached 333 g'.

(2): Due to rapid weight loss of animals during initial 2 weeks of treatment, the concentration of OTA in diet was adjusted from 0, 1, 15, 40 mg/kg diet (weeks 1–2) to 0, 0.5, 2, or 10 mg/kg diet for the remaining exposure period (weeks 3–26). Mean daily OTA intake during week 1 was 0, 0.12, 1.44, 4.42 mg/kg bw (p53+/+) and 0, 0.09, 1.30, 3.94 mg/kg bw (p53+/-). Mean daily OTA intake in weeks 3–26 was 0, 0.03, 0.20, 1.46 mg/kg bw (p53+/+) and 0, 0.03, 0.19, 1.55 mg/kg bw (p53+/-).

(3): Note that the study authors designated an LOEL, but the CONTAM Panel considers this a LOAEL.

4.2.4. Genotoxicity

4.2.4.1. Introduction

In the previous EFSA opinion on OTA (EFSA, 2006), the CONTAM Panel concluded that 'DNA damage and genotoxic effects of OTA were most likely attributable to cellular oxidative damage and within the limit of sensitivity of the analytical procedures, there was no clear evidence for the formation of specific OTA-containing DNA adducts'. The evidence available at the time included:

a) negative mutation assays in *Salmonella* Typhimurium tester strains (with exception of a single study reporting positive results in TA1535, TA98 and TA1538 strains incubated with murine kidney microsomes in the presence of either NADP or arachidonic acid as cofactors (Obrecht-Pflumio et al., 1999),

b) *in vitro* evidence of increased mutations in V79 cells, and

c) increased micronuclei and single strand breaks (SSBs) seen in comet assays *in vitro*.

Few *in vivo* studies were available at the time. Here we review data published from 2006 to 2018 addressing the potential genotoxicity of OTA both in cultured mammalian cells and animal models. The findings are summarised below, and further details are presented in Tables 7 (*in vitro* studies) and 8 (*in vivo* studies).

4.2.4.2. *In vitro* genotoxicity studies

No mutagenicity assays in *S. Typhimurium* published after 2006 were identified. In contrast, the genotoxic potential of OTA has been extensively investigated in comet assays with induction of SSBs as endpoint. Positive results were reported in established rodent, porcine, canine, bovine, green monkey and human cell lines as well as in primary cultures. Several of these cell lines are of kidney origin (see Table 8). With a single exception (SimarroDoorten et al., 2006), SSB induction was observed in the absence of rat liver S9. It is possible that some of these OTA-associated SSBs are secondary to oxidative stress. Inclusion of formamido-pyrimidine-DNA glycosylase (Fpg)/endonuclease III (EndoIII) digestion in the Comet assays to reveal the presence of oxidised purines and pyrimidines, increased the yield of SSBs. This observation is consistent with oxidative DNA damage (Arbillaga et al., 2007; Ali et al., 2011, 2014; Costa et al., 2016). The induction of DNA 8-hydroxydeoxyguanosine (8-OHdG) by OTA-treatment of cells was confirmed by direct measurements (Liu et al., 2012; Cui et al., 2013; Rutigliano et al., 2015; Giromini et al., 2016). Consistent with these findings, OTA exposure increased the levels of cellular reactive oxygen species (ROS) (SimarroDoorten et al., 2006; Arbillaga et al., 2007; Liu et al., 2012; Cui et al., 2013; Yang et al., 2014; Bhat et al., 2016).

Several studies reported evidence of OTA-induced micronuclei, chromosomal aberrations and double strand breaks (DSBs) (Ali et al., 2011; Liu et al., 2012, 2015; Ramyaa and Padma, 2013; González-Arias et al., 2014; Lian et al., 2014; Yang et al., 2014). DSBs were associated with a pronounced gap phase 2 (G2) arrest, ATM (ataxia telangiectasia mutated), CHK2 (checkpoint kinase 2) and p53 phosphorylation and decreased expression of several cyclins (see also Section 3.3 on Mode of Action). OTA also induced aberrant mitoses, chromosome hypercondensation with abnormally separated chromatids, asymmetric/multipolar mitotic spindles as well as endoreduplications and polyploidy (Rached et al., 2006; Mosesso et al., 2008; Cosimi et al., 2009; Czakai et al., 2011). Sister Chromatid Exchange (SCE) formation was not consistently associated with OTA exposure (Mosesso et al., 2008; Anninou et al., 2014).

OTA induced mutations in the *Hprt* gene of V79 cells (Palma et al., 2007) and at the L5178Y *tk* locus (Palma et al., 2007; Ali et al., 2014). Sequencing of *Hprt* mutants indicated that the OTA-induced and spontaneous mutational spectra were similar. Analysis of OTA-induced *Tk* mutant colonies revealed both point mutations and large chromosomal rearrangements. Increased mutation frequencies were also observed in the *SupF* gene in a plasmid treated *in vitro* with OTA and transfected into the human kidney Ad293 cell line (Akman et al., 2012).

Table 7: *In vitro* studies on OTA genotoxicity

Test system	Cells	Concentration/ Treatment time	Results	Comments	Reference
SSBs by comet assays	NIH/3T3 cells expressing human CYP450s, 1A1, 1A2, 2C9, 3A4 and human oxidoreductase (hOR)	10, 25, 50, 100, 150, 200 μ M (8 h)	Positive: Only in CYP2C9-hOR. No toxicity (MTT and neutral red, no data presented)	Increased ROS. Poor presentation of the results	SimarroDoorten et al. (2006)
SSBs by comet assays +/- Fpg/EndoIII	Human renal proximal tubular epithelial cells (HK-2)	50, 100, 200, 400, 600 μ M +/- rat liver S9 (3 and 6 h)	Positive: Slight increase at 6 h (400 and 600 μ M, 50–60% survival); Survival and SSB unaffected by S9; SSB increased by Fpg and EndoIII (unconvincing data)	Increased ROS levels; slight protection by NAC	Arbillaga et al. (2007)
SSBs by comet assays, polyploidy by flow cytometry	CHO cells	0.2, 0.8, 1 mM (3 h)	Positive: Comet assay. Extremely toxic doses (cytotoxic at > 10 μ M) Positive: polyploidy	Dose-dependent inhibition of TopoII (<i>in vitro</i> assay)	Cosimi et al. (2009)
SSBs in comet assays; DSBs in γ H2AX assay 8-OHdG with HPLC-ECD	Human peripheral blood mononuclear cells	5, 10, 20 μ M (24 h)	Positive: SSB, DSBs, 8-OHdG (dose-dependent increases). No information on the toxicity of the treatment	Increased ROS at all doses. SSB partially inhibited by NAC-pre-treatment. Accumulation in G1 phase	Liu et al. (2012)
SSB by comet assays, DSBs with γ H2AX (IF detection and western blotting), 8-OHdG detection with HPLC-ECD	Human gastric cell line (GES-1)	5, 10, 20 μ M (24 h)	Positive: SSB, DSBs, 8-OHdG (dose-dependent increases). No information on the toxicity of the treatment	Increased ROS; G2 phase arrest; Phosphorylation of ATM, CHK2, p53	Cui et al. (2013)
SSBs in comet assays +/- pg; MN	CHO and human TK6 cells	MN: 5, 7.5, 10, 12.5, 15, 17.5, 20, 22.5, 25 μ M (24-27 h). Comet assays: 5, 10, 20, 30, 40, 50 μ M (4 h)	Positive: SSB +/- Fpg in TK6 Positive: SSB only + Fpg in CHO cells Positive: MN in TK6 and possibly in CHO cells (borderline levels of toxicity)	Hypodiploid cells in both cell lines (scored in the MN, assays). Evidence of both direct and indirect DNA damage	Ali et al. (2011)
SSBs by comet assays; MN	Green monkey kidney Vero cell line	10 μ M (24 h)	Positive: SSB Positive: MN. Experiments at 80% survival	Limitation: Single dose observations	Ramyaa and Padma (2013)
SSBs in comet assays; MN	Human lymphocytes	Comet assays: 0.075, 0.15, 1.5, 5, 15 μ M; MN: 0.075, 0.15, 1.5, 5 μ M (3 h)	Positive: Small increases in SSB at single points, no dose response Positive: Small increases in micronuclei (1.5 and 5 μ M). Experiments at > 80% survival		González-Arias et al. (2014)

Test system	Cells	Concentration/ Treatment time	Results	Comments	Reference
SSBs in comet assays; DSBs by γ H2AX	Human embryonic kidney cells (HEK 293)	12.5, 25, 50 μ M (24 h)	Positive: Dose-dependent increase in SSB and DSBs. Limited toxicity (MTT assay)	Increased ROS; cell cycle arrest at S phase; downregulation of S-phase proteins (Cyclin A2 and E1 and CDK2); decreased mitochondrial membrane potential	Yang et al. (2014)
SSBs in comet assays; CA	Human oesophageal epithelium immortalised cells (Het-1A)	2.5, 5, 10, 20 μ M (24 h)	Positive: dose response increase in SSB (IC ₅₀ : 65.9 μ M in MTT assay) Positive: dose response increase in CA	G2 phase arrest (10–20 μ M). Decreased expression of Cyclin B1, Cdc2 and Phospho-Cdc2	Liu et al. (2015)
SSBs in comet assays	Porcine epithelial kidney PK15 cells; human leucocytes	1 and 5 μ M (1 and 24 h)	Positive: dose- and time-dependent increases (both cell lines). Non-toxic doses by MTT assay	Combined effects with BEA	Klarić et al. (2010)
SSBs in comet assays	Primary rat hepatocytes	2, 4, 6 nM (12 h)	Positive: at 4 and 6 nM (viability with MTT: 78% and 62%, respectively)	Limited study	Goyary et al. (2014)
SSBs in comet assays	Human peripheral blood lymphocytes	1, 2, 4 μ M (1 h)	Positive: SSB only at 4 μ M/L (no toxicity with ethidium bromide/acridine orange)	Prevention by sodium copper chlorophyllin. Limited study	Domijan et al. (2015)
SSBs in comet assays Plasmid DNA damage assay	Mouse neuroblastoma Neuro-2a cell line	100, 250, 500 nM (24 h)	Positive: All doses (toxicity > 50%). Plasmid DNA damage assay (non-informative)	Increased ROS; Small protection by NAC	Bhat et al. (2016)
SSBs by comet assays +/- Fpg; MN	Green monkey kidney Vero cell line	7.5, 15, 25, 50 μ M (24 h)	Positive: SSB (only at 15 μ M in the presence of Fpg) Positive: MN (only at 25 μ M)	No dose response in MN and comet assays. Limited information	Costa et al. (2016)
DSBs by γ H2AX (western blotting)	Human gastric cells (GES-1)	5, 10, 20 μ M (24 h)	Positive: DSBs (small increase at 20 μ M). No information on toxicity	Decreased Rad51 levels. Overexpression of Rad51 decreases OTA-induced DSBs. Limited study	Lian et al. (2014)
MN	V79 cells and primary porcine urothelial bladder epithelial cells (PUBEC)	0.01, 0.03, 0.1, 0.3, 1, 3, 10 μ M (18 and 24 h for V79, 24 h for PUBEC)	Positive: V79 (0.3–10 μ M but no dose response); PUBEC (3–10 μ M)	Unclear levels of toxicity	Föllmann et al. (2007)

Test system	Cells	Concentration/ Treatment time	Results	Comments	Reference
MN, SCE, CA endoreduplication, polyploidy	Human lymphocytes; V79 cells	23.6-1149 μ M (+/- rat kidney and liver S9)	Negative: SCEs, MN, CA Positive: Endoreduplications and polyploidy (V79 + kidney S9); (human lymphocytes +/- liver S9)	Metaphases with abnormally separated chromatids	Mosesso et al. (2008)
Aberrant mitoses	Immortalised human kidney epithelial cells (IHKE)	1, 10, 50 μ M (12 and 24 h)	Positive: Dose-response increase in giant cells with enlarged/multiple nuclei. Asymmetric/multipolar mitotic spindles	Inhibition of microtubule assembly in a cell-free <i>in vitro</i> assay (200 & 400 μ M)	Rached et al. (2006)
Chromosome condensation and loss of sister chromatid separation	Immortalised human kidney epithelial cells (IHKE)	0, 1, 5, 10, 25, 50 μ M (up to 15 h)	Positive: Chromosome over-condensation and aberrant separation of sister chromatids	Decreased phosphorylation of histone H3Th3 and decreased acetylation of histones H3 and H4	Czakai et al. (2011)
MN	Porcine epithelial kidney cells (PK15)	0.05, 0.5, 5 μ g/mL (corresponding to 0.12, 1.25, 12.5 μ M (24 and 48 h)	Positive: All concentrations: No information on toxicity	Combined effects with BEA and FB ₁	Klarić et al. (2008)
SCEs	Human hepatocellular carcinoma cells (Hep3B)	10^{-12} – 2×10^{-4} M (72 h)	Positive: range 10^{-12} – $\times 10^{-6}$ M. No dose response; no information on toxicity (by MTT only at 24 and 48 h)	Combined effects with sterigmatocystin and citrinin	Anninou et al. (2014)
Mutations at <i>Hprt</i> and <i>Tk</i> genes	Chinese hamster V79 cells and mouse lymphoma cells (L5178Y)	V79 (7, 11, 20, 35, 46, 108, 251 μ M; 3h and 24 h); +/- rat kidney and liver S9 L5178Y (3, 81, 188, 438 μ M, 3 h) +/- rat kidney S9	Positive: Increased mutation frequency in both cell lines. No effects of S9. Mutational spectrum similar to the endogenous one (V79); point mutations and large deletions (L5178Y)	G2-phase/M-phase cell cycle arrest (V79 cells)	Palma et al. (2007)
Mutations in the <i>SupF</i> gene in plasmid Ps189	Human embryonic kidney cells (Ad293)	0.5, 1, 5 μ M +/- rat liver microsomes or Fe (III)/Cu(II) metals	Positive: All doses, only + S9 or metal activation. (OTHQ: positive without metabolic activation)	No dose response. No proper controls for metal activation	Akman et al. (2012)
Mutations <i>Tk</i> ^{+/-} SSB by comet assays +/- Fpg	Mouse lymphoma cells (L5178Y)	0, 5, 10, 25, 50, 100 μ M +/- S9 rat liver (4 h)	Positive: Dose-dependent increase in mutations (from 25 μ M) Positive: Dose-dependent increase in SSB (increased by Fpg). No effect of S9 for both endpoints	Large colonies (gene mutations). All assays at survival levels > 70%	Ali et al. (2014)

Test system	Cells	Concentration/ Treatment time	Results	Comments	Reference
8-OHdG by oxyblot	Canine umbilical cord matrix-mesenchymal stem cells (UCM-MSC)	0.025, 2.5 nM (4 and 7 days)	Positive: Similar increases in DNA 8-OHdG levels at 0.025 and 2.5 nM. Less than 50% cell growth and cells showing fragmented chromatin		Rutigliano et al. (2015)
8-OHdG by oxyblot	Bovine mammary epithelial (BME-UV1) cells; Madin-Darby canine kidney cells (MDCK)	0.3, 0.6, 1.25 µg/mL (corresponding to 0.75, 1.5, 3.1 µM)	Positive: BME-UV1 (only 1.25 µg/mL, survival 40%) Negative: MDCK (range survival 100%–20%)	No changes in the global content of 5-meC	Giromini et al. (2016)
AP sites	Rat kidney cells (NRK) and rat hepatocytes	3, 6 µM (24 h)	Positive: similar increases at 3 and 6 µM (unclear toxicity)	Non-standard test	Cavin et al. (2007, 2009)
UDS	Swine lymphocytes, swine kidney cells (SK6)	0.01–50 µM (72 h)	Positive: swine lymphocytes (1 and 2 µM, cytotoxic concentration > 5 µM) Positive: SK6 (0.5–4 µM)		Stec et al. (2006)

8-OHdG: 8-hydroxydeoxyguanosine; AP: Apurinic/aprimidinic; ATM; ataxia telangiectasia mutated gene; BEA: Beauvericin; CA: chromosome aberrations; cdc2; cell division control protein; CDK2: cyclin-dependent kinase 2; CHK2; checkpoint kinase 2; CHO; Chinese hamster ovary; CTN: citrinin; CYP450: cytochrome P-450; DSBs: Double strand breaks; EndoIII: endonuclease III; FB₁: Fumonisin B₁; fpg; formamido-pyrimidine-DNA glycosylase; γH2AX: Histone variant H2AX in which the Ser-139 residue variant is phosphorylated (an early cellular response to induction of DSBs); G2: gap phase 2; HPLC-ECD: High-Performance Liquid Chromatography with Electrochemical Detection; IF: immunofluorescence; MN: micronuclei; MTT; 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide; NAC: N-acetyl-L-cysteine; OTHQ: ochratoxin hydroquinone metabolite; p53; tumour protein p53; ROS: reactive oxygen species; SSBs: single strand breaks; SCE: sister chromatid exchange; *SupF*: *E. coli* tyrosine amber suppressor tRNA gene; *Tk*: Thymidin kinase; TopoII; topoisomerase II; UDS: unscheduled DNA synthesis; V79 cells: Chinese hamster lung cells clone V79.

4.2.4.3. *In vivo* genotoxicity studies

OTA exposure increased SSBs levels in kidneys of both rats and mice (Mally et al., 2005b; Domijan et al., 2006; Kuroda et al., 2014, 2015), with the single exception of a negative report in rats (Enciso et al., 2018). These positive results were confirmed in a series of more limited studies in which the synergistic and/or antagonistic effects of other chemicals (including mycotoxins) on single-dose exposures to OTA were investigated (Aydin et al., 2013; Cariddi et al., 2015; Corcuera et al., 2015). In one report, Comet assays detection of OTA-induced SSBs was possible only following DNA digestion with Fpg/EndoIII (Corcuera et al., 2015), although a direct increase in SSBs levels was reported in other studies (Mally et al., 2005b; Domijan et al., 2006). Overall these findings are consistent with the induction of oxidative DNA damage by OTA exposure *in vivo*. However, the few reports that addressed this possibility by direct measurements of rat kidney DNA 8-OHdG were generally negative (Mally et al., 2005a; Hibi et al., 2011; Zhu et al., 2016a). With regard to non-kidney tissues, there are both negative and positive results of OTA-induced SSBs formation in rat liver (Mally et al., 2005b; Aydin et al., 2013; Corcuera et al., 2015), rat lymphocytes and spleen and mouse blood (Mally et al., 2005b; Aydin et al., 2013; Cariddi et al., 2015).

There are several reports of OTA-induced DSBs (as measured by immunofluorescence or western blotting) in the tubular epithelial cells located in the outer stripe of the renal outer medulla of mouse and rat kidneys (Taniai et al., 2012a; Kuroda et al., 2014, 2015).

The impact of p53 status on OTA-induced DNA breakage was investigated in mouse kidney. The levels of OTA-induced SSBs were similar in p53^{+/+} and p53^{-/-} mice. The frequencies of DSBs were, however, significantly higher in p53^{-/-} mice. The authors suggest that p53 protein plays a major role in preventing the progression of OTA-induced DNA damage into DSBs (Kuroda et al., 2015).

Whether OTA can induce chromosomal damage in the bone marrow remains unclear. Conflicting data on OTA induction of micronuclei have been obtained in mice (Cariddi et al., 2015) and rats (Abdel-Wahhab et al., 2008; Corcuera et al., 2015; Zhu et al., 2016a). A single study reported increased chromosomal aberrations in the bone marrow of treated mice (Bouslimi et al., 2008). No increase of chromosome aberrations was observed in splenocytes of OTA-treated rats (Mally et al., 2005b). In the same study, a dose-dependent increase in hyperdiploid cells was observed in the renal medulla, but not in cortical regions, of kidneys from OTA-treated animals.

Mutation induction by OTA has been thoroughly investigated in rat (Hibi et al., 2011; Kuroda et al., 2014) and mouse (Hibi et al., 2013b; Kuroda et al., 2015) kidney. In rats, mutations were analysed at the *Gpt* and *Red/Gam* (Spi- mutants) loci. The latter assay selectively detects deletion and frameshift mutations. After a 4- or 13-week OTA treatment, no mutations were identified in the cortex. After a 4-week OTA treatment, an increased frequency of Spi- (but not *Gpt*) mutant was specifically observed at the carcinogenic target site, i.e. in the outer medulla. OTA treatment was associated with deletions (1-6kb), insertions as well as base substitutions (Hibi et al., 2013b). No cortical changes or increased levels of DNA 8-oxodG were observed in the outer medulla (Hibi et al., 2011).

The role of p53 in OTA-induced mutagenesis was also investigated in p53^{+/+} and p53^{-/-} mice (Hibi et al., 2013b; Kuroda et al., 2015). OTA-induced mutagenesis was only observed in p53-deficient mouse kidneys. Mutations were confined to the *Red/Gam* locus and were not observed at the *Gpt* locus. The spectrum of OTA-induced Spi-mutants comprised single base deletions at G/C repetitive sequences, single base substitutions and insertions. The authors noted that the mutational spectra in rats and p53^{-/-} mice were only partially overlapping.

4.2.4.4. DNA adduct formation

The possible formation of specific OTA-induced DNA adducts remains highly controversial. An oxidative pathway leading to covalent OTA-DNA adducts *via* biotransformation of OTA to the quinone OTQ (see Figure 5) has been proposed (Pfohl-Leschkowitz and Manderville, 2012). *In vitro* reaction of the synthetic OTA hydroquinone OTHQ (see Figure 5) with DNA was reported to give rise to adduct spots detected by ³²P-post-labelling (Tozlovanu et al., 2006). The chemical structure of the adducts was not identified. The DNA adduct spots ascribed to covalent attachment of the OTQ electrophile generated by OTHQ autoxidation were also detected by ³²P post-labelling after *in vitro* OTA treatment of salmon sperm DNA (in the presence of microsomes/NADH) as well as in WI26 and HK2 human cell lines (Tozlovanu et al., 2006). A further adduct spot observed by ³²P-post-labelling in human kidney cells and *in vivo* in the kidneys of OTA-treated rats was reported to co-migrate with a post-labelled carbon-linked C8 OTA-3'dGMP adduct standard generated by photoreaction of OTA with DNA (Tozlovanu et al., 2006; Mantle et al., 2010b). This adduct was proposed to be formed via reductive

dehalogenation of OTA to generate an aryl radical (see Figure 5) that reacts with the C8 site of dG (Pfohl-Leskowicz and Manderville, 2012). The levels of this principle adduct in rat kidney were reported to be in the range of $20\text{--}70 \times 10^9$ nucleotides (Mantle et al., 2010b). However, these results in rat kidneys were not reproduced by other laboratories using ^{32}P post-labelling and stable isotope dilution LC-MS/MS with an LOD of $3.5 \text{ OTA-dG} \times 10^9$ nucleotides (Mally et al., 2005a,b; Delatour et al., 2008).

An approach based on structure–activity relationships proposed a dissociation between the cytotoxic and mutagenic properties of OTA with the first one being due to ROS production and the second one to DNA adduction (Hadjeba-Medjdoub et al., 2012). More recently, molecular modelling studies (molecular dynamics simulations) were used to predict the impact of the sequence context of OTA-dG adducts on their mutagenic potential (Kathuria et al., 2017, 2018). Finally, oligonucleotides containing C-linked C8 aryl-dG model adducts, inserted in the *NarI* sequence, were used in primer extension assays with model DNA polymerases for investigating the levels of base misincorporation and DNA polymerases blockage and slippage (Manderville and Wetmore, 2017). Evidence of stalled DNA replication possibly leading to deletions and base substitution mutations at repetitive sequences were obtained (Sproviero et al., 2014). It remains unclear whether and to what extent these DNA adducts are formed *in vivo* and which metabolic pathway(s) are responsible for the formation. In any event, it seems unlikely that these very low numbers of DNA adducts could contribute significantly to either the observed DNA breakage or mutation.

Table 8: *In vivo* studies on OTA genotoxicity

Test system	Animals	Concentration/Treatment	Result	Comments	Reference
SSBs by comet assays +/- <i>Fpg</i> (kidney)	Wistar rats (males)	0.005, 0.05 and 0.5 mg/kg bw/15 days (oral)	Positive: all doses. SSBs increased by <i>Fpg</i>	Combined effects with FB ₁ : synergistic increase in SSB	Domijan et al. (2006)
SSBs by comet assays in liver, kidney, lymphocytes	Sprague–Dawley rat (males)	0.5 mg/kg bw/14 days (gavage)	Positive: liver & kidney Negative: lymphocytes	Protection by lycopene	Aydin et al. (2013)
SSBs by comet assays +/- <i>Fpg</i> in kidney	Fisher rats (males & females)	0.5 mg/kg bw/7 days 0.21 and 0.5 mg/kg bw/21 days (gavage)	Negative: in both males and females	No changes in total GST and SOD activity, total GSH and GSSG levels	Enciso et al. (2018)
SSBs by comet assays +/- hOGG1 in kidney and liver	Wistar rats (males)	0.125 and 0.250 mg/kg bw/21 days (gavage)	Negative: kidney Positive: liver (only at highest doses) but no control data for comet assays are provided	Combined effects with CTN Limited value (no controls)	Rašić et al. (2018)
SSBs by comet assays in kidney	Wistar rats (female)	0.5 mg/kg bw/7, 14, and 21 days (i.p.)	Positive	Unreliable study (0 values in controls)	Zeljezić et al. (2006)
SSBs by comet assays assays +/- <i>Fpg</i> (kidney, liver, spleen, blood) CA in splenocytes	Wistar rats (males)	OTA: 0.25, 0.5, 1 and 2 mg/kg bw/2 weeks (oral) OTB: 2 mg/kg bw/2 weeks (oral)	Positive (OTA): SSBs in kidney (all doses), liver and spleen (0.5–2 mg/kg). Increased by <i>Fpg</i> in liver and blood (all doses), kidney (only highest dose) Negative (OTA): CA in splenocytes (non-significant increase)	Increased polyploidy in renal medulla (but not in cortical regions of the kidney) OTB-induced SSBs only in liver and spleen	Mally et al. (2005b)
SSBs by comet assays in blood, micronuclei in bone marrow	BALB/c mice (males)	0.85 mg/kg bw i.p. Analyses at 24 h	Positive: SSBs in blood Positive: micronuclei in bone marrow	Combined effects with Polyphenols. Limited study (single dose)	Cariddi et al. (2015)
SSBs by comet assays +/- <i>Fpg</i> in liver and kidney Micronuclei in bone marrow	F344 rats (males)	0.5 mg/kg bw/3h and 24 h (oral). No clinical signs of toxicity	Positive: SSBs in kidney (only + <i>Fpg</i>) Negative: SSBs in liver Negative: micronuclei	Combined treatment with AFB ₁ : antagonistic effects	Corcuera et al. (2015)
Micronuclei in bone marrow	Sprague–Dawley rats (males)	3 mg/kg bw/15 days (oral)	Positive: single and very high dose (30% of death in OTA group)	Combined treatment with plant extracts (Inulacrithmoides). Limited study	Abdel-Wahhab et al. (2008)
DSBs by γ H2AX	F344 rats (males)	0.21 mg/kg bw/28 days (gavage)	Positive: DSBs in outer stripe of outer medulla	Increased cdc-2-positive and P-Chk2 cells. Karyomegaly in outer medulla	Taniai et al. (2012a)

Test system	Animals	Concentration/Treatment	Result	Comments	Reference
CA in bone marrow	BALB/c (males)	0.6, 1.2, and 2.4 mg/kg bw (corresponding to 2, 4, and 8% of the mouse LD50, 31 mg/kg bw) (sacrifice 24 h after single ip injection)	Positive: dose-response increase in CA at 1.2 and 2.4 mg/kg bw (no statistical significance provided)		Bouslimi et al. (2008)
Mutations in <i>Gpt</i> and <i>Red/Gam</i> genes (Spi^-) in kidney	<i>Gpt</i> -delta F344 rats (males & females)	5 ppm (gavage)/4 & 13 wks (corresponding to 0.36–0.38 mg/kg bw/4 wks and 32.7–34 mg/kg bw/13 wks for males & females, respectively). Decreased absolute/relative kidney weights (both times)	Negative: <i>gpt</i> and Spi^- mutations in the whole kidney (4 and 13 wks). No changes in mutational spectra of <i>gpt</i> mutants Positive: Spi^- mutations in outer medulla, but not in inner medulla or renal cortex (4 wks)	Karyomegaly in outer medulla (both times) No increase in DNA 8-OHdG levels in the cortex or outer medulla (13 wks)	Hibi et al. (2011)
Mutations in <i>Gpt</i> and <i>Red/Gam</i> (Spi^-) in kidney	<i>Gpt</i> -delta $p53^{+/+}$ and $p53^{-/-}$ C57BL/6J mouse	1 and 5 mg/kg bw/4 weeks (gavage)(males). Decreased body weights & absolute/relative kidney weights (highest dose)	Negative: no increase in mutation frequency at both loci in $p53^{+/+}$ mice. No difference in mutational spectra at <i>Gpt</i> Positive: increased Spi^- mutations in $p53^{-/-}$ mice in outer medulla (only at 5 mg/kg bw)	Increased $p53$ in $p53^{+/+}$ (5 mg/kg bw). Higher levels of apoptosis & karyomegaly in $p53^{-/-}$ kidneys (evident also in the cortex)	Hibi et al. (2013b)
Mutations in <i>Red/Gam</i> (Spi^-) SSBs by comet assays, DSBs by γ -H2AX (IF and western blotting) in kidney outer medulla	<i>Gpt</i> -delta F344 rats (males)	Spi^- mutations: 5 ppm/4 weeks (0.36 mg/kg bw) SSBs & DSBs: 0.07, 0.21, 0.63 mg/kg bw/4 weeks (gavage)	Positive: Increased Spi^- mutation frequency in outer medulla (large deletions, range 1–6 kb) Positive: SSBs (all doses) Positive: DSBs (2 highest doses)	Dose-dependent increased expression of homologous recombination genes and genes involved in G_2/M arrest and S/G_2 phase	Kuroda et al. (2014)
Mutations in <i>Red/Gam</i> (Spi^-), SSBs by comet assays, DSBs by γ -H2AX in kidney	<i>Gpt</i> -delta $p53^{+/+}$ and $p53^{-/-}$ C57BL/6J mouse (males)	Spi^- mutations & DSBs: 5 mg/kg bw/4 wks SSBs: 5 mg/kg bw/3 days (gavage)	Positive: increased Spi^- mutations only in $p53^{-/-}$ mice (single bp deletions in repetitive G/C sequences, insertions and base substitutions) Positive: SSBs (no difference $p53^{+/+}/p53^{-/-}$ mice) Positive: DSBs (preferentially in outer medulla of $p53^{+/+}$ mice). Higher DSBs in $p53^{-/-}$ mice (also in the cortex)	Increased apoptotic & karyomegalic cells (higher in $p53^{-/-}$ mice) Several differentially expressed genes affected by $p53$ status identified by global expression analysis by microarrays	Kuroda et al. (2015)
DNA 8-OHdG by LC/MS/MS in liver and kidney	F344 rats (males)	0.25, 0.5, 1, 2 mg/kg bw/2 weeks (oral)	Negative	Increased apoptosis and polyploidy in cells of outer stripe of outer medulla	Mally et al. (2005a)

Test system	Animals	Concentration/Treatment	Result	Comments	Reference
Micronuclei in bone marrow 8-OHdG by HPLC/ECD in kidney and liver	Wistar rats (males)	1 and 4 mg/kg bw/7 days	Negative: both micronuclei & 8-OHdG	No consistent evidence of oxidative stress in the liver or kidney (ROS, SOD, GSH, MDA)	Zhu et al. (2016a)
8-OHdG by HPLC/ECD in kidney and liver SSB by comet assays	Fisher 344 Rats (males)	70 and 210 µg/kg bw/4 weeks and 13 weeks	Positive: 8-OHdG in liver (only at 4 weeks, both doses, no dose response) Positive: 8-OHdG in kidney (only at 13 weeks, both doses, no dose response)	Negative: SSB (but data not shown)	Qi et al. (2014a)
AP sites in kidney	Fisher 344 Rats (males)	Diet containing 300 µg//kg bw decreased to 100 µg/rat after animals reached 333 g (21 days and 12 months)	Negative: 21 days Positive: 12 months	Non-standard test	Cavin et al. (2007)

AFB₁: Aflatoxin B₁; AP: purinic/aprimidinic; CA: Chromosome aberrations; CTN: citrinin; γ-H2AX: phosphorylated form of histone protein of the H2A family formed when double-strand breaks appear. *Gpt*: Glutamic-pyruvic transaminase gene; GST: Glutathione-S-transferase; SOD: Superoxide dismutase; *Sp1*: protein spitz precursor (a proto oncogene); GST: Glutathione synthetase; GSSG: Glutathione disulfide; 8-OHdG: 8-hydroxydeoxyguanosine; DSBs: Double strand breaks; hOR: human oxidoreductase; FB₁: Fumonisin B₁; *Fpg*: Fapy glycosylase gene; ROS: reactive oxygen species; MDA: Malondialdehyde; SSBs: Single strand breaks; STER: Sterigmatocystin.

4.2.4.5. Summary of genotoxicity

OTA exposure induces SSBs, DSBs and chromosome damage in numerous mammalian cell lines and in primary cultures from various tissues. DNA break induction does not require metabolic activation. Since OTA increases *in vitro* levels of ROS and DNA 8-OHdG, some OTA-associated SSBs may be secondary to oxidative stress. SSBs induced in rat kidney may be associated with pathological findings, although these are not accompanied by measurable increases in DNA 8-OHdG.

OTA induces a narrow spectrum of chromosomal damage: chromosome hypercondensation, abnormally separated chromatids, multipolar mitotic spindles, endoreduplications, polyploidy and aneuploidy. Importantly, aberrant mitoses and karyomegaly were concentrated in the target area for OTA carcinogenesis (the kidney outer medulla).

OTA is a weak mutagen *in vitro* and *in vivo*. Mutations restricted to the cancer target site are detected in rats after a short (4 weeks) exposure to a carcinogenic OTA dose. Large deletions and base substitutions are the main mutagenic events. DNA 8-OHdG at the carcinogenic target site was not detectable. The mutational spectrum in the kidney of OTA-treated p53^{-/-} mice is similar.

The molecular mechanism underlying OTA genotoxicity remains unclear. The formation of covalent OTA-DNA adducts remains controversial. The extremely low reported levels of DNA adducts (10/10⁹ nucleotides) are difficult to reconcile with the genotoxic effects of OTA and the proposed OTA-DNA adducts are likely to be, at best, minor contributors. Nevertheless, the OTA-induced mutations in rat and mouse kidneys are clearly not a simple consequence of oxidative DNA damage.

The mechanism underlying OTA-induced chromosomal damage is also unclear. Abnormal anaphase figures might derive from unresolved 'replication stress' with break-induced recombination of DSBs in the early stage of mitosis. In addition, aberrant chromosome segregation and cell division may reflect damage to the mitotic spindle.

4.2.5. Reproductive toxicity

In their opinion of 2006, EFSA noted that no adequate studies on reproductive toxicity with OTA were available but that several studies described in previous assessments (FAO/WHO, 1991, 1996, 2001; SCF, 1998) together with recently published studies suggest that OTA is teratogenic in rodents (EFSA, 2006). It was also noted that the lowest teratogenic dose in rodents was about 12 times higher than the LOAEL identified for OTA (8 µg/kg bw per day for renal effects in a 90-day study with pigs). Table 9 presents new *in vivo* studies on reproductive toxicity published after the last EFSA evaluation.

Table 9: *In vivo* reproductive and developmental toxicity studies published since 2006

Animals	Study design	Observations	Effect level	Reference
Pregnant Wistar rats	<p>Preliminary study: Gavage; single doses of 0.0, 2.0, 2.5, 2.75, 3.0, 3.5 and 4.0 mg OTA/kg bw on one day in the period of GD 6–15. Sacrifice on GD 20</p> <p>Main study: Gavage, single doses of 0.0 and 2.75 mg OTA/kg bw per day in the period of GD 6–15. Sacrifice on GD 20. N = 10 per group</p>	<p>Preliminary study: Doses of ≥ 3.0 mg/kg bw: pronounced maternal and developmental toxicity</p> <p>Doses of ≤ 2.0 mg/kg bw: no effects</p> <p>Main study:</p> <p>Dams: anorexia, polydipsia, polyuria, lacrimation, in particular when treated on GD6–8. Resorptions and post implantation loss when treated on GD6–7</p> <p>Fetuses: Hydrocephaly, incomplete closure of skull and omphalocele, microphthalmia, enlarged renal pelvis and renal hypoplasia; malformed skulls, sternebrae, vertebrae, ribs, in particular in dams treated on GD6–7</p>	2.75 mg OTA/kg bw per day (only one dose level tested)	Patil et al. (2006)
Male and female 45–49 days old Fischer rats	<p>Diet, 0.0, 0.16, 0.4, 1.0 and 2.5 mg OTA/kg feed, corresponding to 0.0, 8.9, 21.7, 55.2 and 141.8 $\mu\text{g}/\text{kg}$ bw per day (males) and 0.0, 11.9, 33.9, 73.3 and 167.0 $\mu\text{g}/\text{kg}$ bw per day (females); From day 1–70 (F0 males and females pre-mating, mating), from day 28–70 (F0 males, pregnant and non-pregnant F0 females); From day 49–70 or PND1–21 (F1 pups). N = 10 per group and sex</p>	<p>F0 males and females: mild increases in severity scores for tubular epithelial cell degeneration at 0.16 and 2.5 mg/kg in females and from 0.4 mg/kg onwards in males</p> <p>F0 males: \downarrow relative kidney weights at 1.0 and 2.5 mg/kg feed. At 2.5 mg/kg feed \uparrow in albumin, sodium, total protein and bilirubin at 2.5 mg/kg feed</p> <p>F0 females: \downarrow relative kidney weights, bw, absolute ovary weight, cholesterol, RBC, haemoglobin, haematocrit, RDW, monocytes, neutrophils</p> <p>\downarrow implantations at 2.5 mg/kg feed</p> <p>In F1 males from dams given 1.0 mg/kg feed \downarrow bw in on PND4, 7, 14, 21;</p> <p>In F1 females from dams given 1.0 mg/kg feed \downarrow bw on PND4, 7;</p> <p>\uparrow tubular degeneration in F1 males of dams given 0.16 mg/kg onward</p> <p>and in F1 females from dams given 0.4 mg/kg onwards; In F1 males from dams given 1.0 mg/kg \downarrow relative kidney/liver weights, \uparrow plasma cholesterol and in F1 males from dams given 0.4 mg/kg \uparrow plasma phosphorous</p> <p>In F1 females from dams given 1.0 mg/kg \downarrow relative liver weight, \uparrow cholesterol and in F1 females from dams given 0.4 mg/kg onwards</p> <p>\downarrow relative kidney weight</p>	<p>The authors set an LOAEL for \downarrow body weight for female F0 rats at 167 $\mu\text{g}/\text{kg}$ bw and a LOAEL for \downarrow kidney weight in F0 males at 55.2 $\mu\text{g}/\text{kg}$ bw per day and for F0 females at 167 $\mu\text{g}/\text{kg}$ bw per day</p> <p>Authors set an LOAEL for \downarrow bw for F1 males and females at 55 and 73.3 $\mu\text{g}/\text{kg}$ bw per day, respectively, was set and an LOAEL for \downarrow relative kidney weight in F1 males at 55 $\mu\text{g}/\text{kg}$ bw per day and for F1 females at 33.9 $\mu\text{g}/\text{kg}$ bw per day</p>	Bondy et al. (2018)
Pregnant rabbits	<p>Diet, 0.0, 0.03, 0.06 mg OTA/kg bw for 15 days (GD 6–20); N = 5 per group</p>	<p>At 0.03 mg/kg bw: \uparrow ALT, \downarrow RBC, \uparrow MCV in dams, \downarrow fetus length and weight</p> <p>At 0.06 mg/kg bw: \uparrow urea, AST, ALT; \downarrow RBC, Hb, PCV; \uparrow MCV in dams, \downarrow fetus length and weight</p> <p>At both doses, dams had mild to moderate degenerative changes (pyknosis, necrosis of glomeruli, congestion of tubular epithelial cells) in kidney, at high dose also accumulation of eosinophilic material. At high dose moderate degenerative changes in the liver (cellular shrinkage, widening of sinusoidal spaces, vacuolation). No effects on the intestine observed</p>	0.03 mg/kg bw per day	Jan et al. (2017)

Animals	Study design	Observations	Effect level	Reference
Young male inbred Swiss albino mice	Gavage, 0.0, 1.5, 3.0 mg/kg bw for 45 days. N = 10 per group	At 1.5 and 3.0 mg OTA/kg bw ↓ sperm count (–22% and –69%), sperm motility (–45% and –72%), sperm viability (–34% and –59%) fertility rate (–50 and –77%)	1500 µg/kg bw per day	Chakraborty and Verma (2010a)
Groups of 12 mated female Crl: CD (SD) rats	Diet, 0.0, 0.12, 0.6, 3.0 mg/kg OTA from GD6-21 (corresponding to 0.0, 8.0, 39.3, 203.6 µg/kg bw per day during gestation and 0.0, 16.1, 76.0 and 378.6 µg/kg bw per day during lactation period). Sacrifice of dams on PND 22. Offspring maintained until PND 77 (27 males and 10 females per group) without OTA. Interim sacrifice of offspring on PND 21 (10 males per group)	No effect on maternal parameters (behaviour, brain and kidney weight) At 3.0 mg/kg bw male and female offspring (F1) showed transient body weight decrease after weaning. Changes in hippocampal neurogenesis-related parameters were seen in males at PND 21. Female and male offspring showed neuroprotective actions against OTA-induced neurogenesis. All changes were reversed by PND77	Authors set the NOAEL for offspring neurogenesis at 0.6 mg OTA/kg feed, corresponding to 39.3–76.0 µg/kg bw per day	Tanaka et al. (2016)

ALT: alanine transaminase; AST: aspartate transaminase; F0: parent generation; F1: first filial generation; F2; second filial generation; GD: gestation day; Hb: haemoglobin; LOAEL: lowest observed adverse effect level; MCV: mean corpuscular volume; NOAEL: no observed adverse effect level; OTA: ochratoxin; PCV; packed cell volume; PND: post-natal day; RBC: red blood cells; RDW: red cell distribution.

Summarising briefly the *in vivo* studies presented in Table 9. A developmental LOAEL of 2.75 mg OTA/kg bw per day can be derived from the study of Patil et al. (2006) and is based on occurrence of malformations paralleled by pronounced maternal toxicity at the single dose for which a thorough toxicological evaluation has been carried out. From the study of Bondy et al. (2018), lower LOAELs for OTA have been identified. The authors set a maternal LOAEL of 167 µg OTA/kg bw per day based on reduced body and kidney weights, while the paternal LOAEL for reduced kidney weights was 55.2 µg OTA/kg bw per day. The corresponding LOAELs for reduced body and kidney weight in male offspring are 141.8 µg OTA/kg bw per day and in females 167 µg and 33.9 µg OTA/kg bw per day, respectively. Mild increases in severity scores for tubular degeneration in males were significant starting from 8.9 µg/kg bw per day and increased with dose. In females, these were significant at 33.9 µg/kg bw per day and at the highest dose. It is not clear from this publication to which extent the offspring was exposed to OTA during lactation (i.e. the relative exposure *via* milk or feed). A maternal and developmental LOAEL of 0.03 mg/kg bw per day (lowest dose tested) can be derived from Jan et al. (2017) based on reduced fetus lengths and weights in the presence of altered blood chemistry in the dams. Tanaka et al. (2016) identified a developmental NOAEL for neurogenesis of 33.9–76.0 µg OTA/kg bw per day. In this study, no effects on behaviour, brain or kidney weight were observed in dams up to the highest dose of 203.6–378.6 µg OTA/kg bw per day. It must be noted that the adverse nature of the parameters used for derivation of a developmental NOAEL is questionable and that these parameters were also not assessed in the dams. Finally, an LOAEL of 1,500 µg/kg bw per day (lowest dose tested) for male fertility can be derived from the study of Chakraborty and Verma (2010a) based on alterations of sperm parameters.

Several *in vitro* studies indicate a teratogenic potential of OTA. Based on a mean half maximal inhibitory concentration (IC₅₀) for cell viability and differentiation of brain cells exposed to 2.52 ± 0.062 µg/mL OTA, it was suggested by the authors that OTA is a strong potential teratogen acting via its general toxicity (Wilk-Zasadna and Minta, 2009). OTA-induced morphological defects (neural tube defects (NTD), stunted limb bud development, curling of tail and hypoplasia of mandibular arches) in rat embryo explants (Balasaheb Wangikar et al., 2007). When mouse oocytes were incubated with OTA before *in vitro* maturation (IVM) or OTA was applied to female mice before collection of the oocytes for IVM, a series of adverse effects was observed in these cells (Huang and Chan, 2016).

4.2.5.1. Summary on reproductive toxicity

The new reproduction studies show that OTA induces developmental toxicity. However, the doses at which effects are observed differ by orders of magnitude in the different investigations and thus LOAELs derived in these studies (albeit for different endpoints and from studies with deviating designs) vary from 33.9 to 2,750 µg OTA/kg bw per day. Notably, adverse effects on offspring are usually paralleled by pronounced maternal toxicity. *In vitro* data suggest that OTA developmental effects might be mediated via its general toxicity which would support the *in vivo* findings. Overall, the new studies corroborate the conclusion of EFSA (2006) that OTA is a developmental toxicant but that developmental effects are generally observed at doses higher than those causing adverse effects in the kidney of pigs (EFSA, 2006).

4.2.6. Observations in humans

4.2.6.1. Balkan Endemic Nephropathy

In previous EFSA (EFSA, 2006) and JECFA (FAO/WHO, 2001, 2008) assessments, it was concluded that the available data from old epidemiological studies did not allow establishing an aetiological link between OTA, BEN and associated urinary tract tumours. It is now generally agreed that these conditions occurring in the Balkan and are rather associated with exposure to toxins other than OTA, i.e. aristolochic acid (Gifford et al., 2017; Jadot et al., 2017).

4.2.6.2. Chronic interstitial nephropathy of unknown aetiology

In 1995, an endemic chronic interstitial nephropathy (CIN) of unknown aetiology with striking similarities with that of BEN was described in Tunisia (Maaroufi et al., 1995). Because of high food contamination levels and high serum or plasma OTA concentrations, the authors suggested that OTA might be related to this group of renal disease. In summary, they reported that in healthy controls, concentrations of OTA ranged from 0.1 to 16.6 µg/kg in food and from 0.1 to 2.3 ng/mL in serum/plasma concentrations, and in nephropathy patients OTA values were 0.3–46,830 µg/kg in food and 0.7–1,136 ng/mL in serum/plasma. In surveys conducted during the 1990s and published later, they

found significantly higher mean serum concentrations of OTA in patient groups with CIN of unknown cause (total $n = 954$, $44.4 \pm 19 \mu\text{g/L}$ to $55.6 \pm 19 \mu\text{g/L}$) than in healthy controls recruited from the general population (total $n = 205$, $1.22 \pm 1.2 \mu\text{g/L}$ to $3.35 \pm 2.32 \mu\text{g/L}$) (note that OTA values in this study was given per L not per mL as in the other studies below) (Abid et al., 2003). This was followed up in a later study (Hassen et al., 2004) on patients and healthy individuals from the centre of Tunisia previously reported to be a hot spot of chronic renal failure with high OTA exposure. In a cross-sectional study, they included 40 patients with CIN of unknown cause, 60 patients with CIN of known aetiology (not specified) and 40 healthy individuals. The percentage of positive OTA plasma samples in the respective groups were 100, 78 and 62%, with OTA concentrations of (mean and SD): $50.4 \pm 8.2 \text{ ng/mL}$ (range: 18.4–171.25 ng/mL), $12.36 \pm 4.4 \text{ ng/mL}$ (range: 1.68–29 ng/mL) and $1.22 \pm 1.2 \text{ ng/mL}$ (range: 0–3.2 ng/mL). The OTA concentrations in the group with unknown aetiology were significantly different from that of both the healthy subjects and the group with known aetiology. The mean levels of β_2 -microglobulinuria in the groups were $1,960 \pm 990 \mu\text{g/L}$, $1,450 \pm 90 \mu\text{g/L}$ and $120 \pm 70 \mu\text{g/L}$, respectively, and the value of the group with unknown aetiology was significantly different from that of both the healthy subjects and the group with known aetiology (Hassen et al., 2004).

Two studies from a second research group investigated plasma or serum concentrations of OTA in patients with renal diseases and in healthy subjects (Hmaissia Khelifa et al., 2008, 2012). In the first study, blood samples were collected from healthy individuals (healthy group, HG) ($n = 105$) and five different groups of nephropathic patients suffering from CIN of known aetiology ($n = 22$), CIN of unknown aetiology (CINI) ($n = 30$), chronic vascular nephropathy (CVN) ($n = 26$), chronic glomerular nephropathy (CGN) ($n = 26$) and renal transplanted subjects (RTS) ($n = 27$). The samples were from various regions of Tunisia. The following fraction of OTA-positive subjects and mean and SD of plasma of the different groups were: HG, 28%, $0.49 \pm 0.67 \text{ ng/mL}$; CIN, 45%, $0.92 \pm 0.83 \text{ ng/mL}$; CINI, 80%, $1.25 \pm 1.22 \text{ ng/mL}$; CVN, 26%, $0.75 \pm 0.88 \text{ ng/mL}$; CGN, 26%, $0.21 \pm 0.14 \text{ ng/mL}$; RTS, 85%, $0.64 \pm 1.38 \text{ ng/mL}$. The CINI group had the highest fraction of OTA-positive individuals and highest OTA plasma value, both being significantly higher than the controls (Hmaissia Khelifa et al., 2008). In the second study, they collected samples from the Military Hospital of Tunisia and determined serum OTA concentrations in healthy subjects ($n = 44$) and patients with CIN of unknown aetiology ($n = 22$). For each group, 44 samples of food consumed every day or several times a week were collected. Analyses of the food samples showed that OTA was detectable in 52.3% of the samples and none of the samples from the healthy controls were above 6.1 ng/g with a mean value of 0.77 ng/g. The corresponding values for the nephropathic patients were 88.6%, 33.8 ng/g and 9.28 ng/g. Of the healthy subjects, the 34% with detectable OTA concentration in serum had a mean value of $0.22 \pm 1.39 \text{ ng/mL}$ (range 0.12–1.5 ng/mL). Eighty per cent of the patients were OTA positive and these had a mean OTA serum value of $1.25 \pm 1.22 \text{ ng/mL}$ (range: 0.12–3.8 ng/mL). Both the fraction of OTA positive and mean serum concentration of OTA were significantly higher than in the controls (Hmaissia Khelifa et al., 2012).

Finally, in an additional cross-sectional study from the first research group, Zaied et al. (2011) measured serum concentration of OTA in blood samples collected in Tunisian hospitals from patient with different chronic renal diseases ($n = 270$, 115 males and 115 females). The renal disease groups included patients with chronic vascular nephropathy ($n = 49$), chronic glomerular nephropathy ($n = 61$) and CIN with known ($n = 77$) and unknown ($n = 83$) aetiology, respectively. Healthy volunteers were included as controls (total, $n = 138$, 91 males and 47 females). The group with CIN of unknown aetiology had the highest rate of OTA positive serum samples, and the highest mean concentration of OTA (18 ng/mL, range: 1.8–65 ng/mL). In comparison, the other groups with renal disease had the following OTA detection rates and mean and range of serum concentrations of OTA: chronic vascular nephropathy, 37%, 5.5, 1.5–16 ng/mL; chronic glomerular nephropathy, 49%, 5.8, 1.1–16.3 ng/mL; CIN with known aetiology, 62%, 5.5, 1.0–21.6 ng/mL. The healthy controls had 49% OTA-positive samples and a mean of 3.3 ng/mL (1.7–8.5 ng/mL). Mean intakes of OTA calculated from serum OTA values were 26 ng/kg bw in the group with CIN of unknown aetiology as compared with around 8 ng/kg bw in the other groups of renal disease and 4.4 ng/kg bw in the control group.

The CONTAM Panel notes that these studies on CIN all conducted in Tunisia, which all had cross-sectional designs, did not allow concluding on a possible causal association between OTA exposure and chronic interstitial nephropathy or other renal diseases.

4.2.6.3. Renal function in children

Hassan et al. (2016) investigated the relationship between OTA in breast milk and maternal and infant serum, and kidney function of infants as assessed by urinary β_2 -microglobulin and

microalbuminuria in mother infant pairs from Egypt. The mean and standard deviation (SD) of the age of the breastfeeding mothers was 27 ± 5.77 years. Their infants were exclusively breast-fed for 4 months. OTA levels in serum and milk were determined using LC with microfluorimetric detection. The limit of detection was not given. Of the 50 mothers included, 36 had detectable OTA concentrations in serum (mean, SD; 4.28 ± 3.97 ng/mL) and milk (mean, SD; 1.89 ± 0.98 ng/mL). All their breastfed infants had detectable OTA in serum (mean, SD; 1.26 ± 1.1 ng/mL). Univariate comparison of infants of women that had non-detectable and detectable level of OTA in serum revealed significant higher urine β 2-microglobulin in the OTA-positive vs. OTA-negative mothers (mean, SD; 260 ± 162.5 μ g/mL and 30.3 ± 7.9 μ g/mL, respectively) and for microalbumin in urine of infants of OTA-positive and OTA-negative mothers (mean, SD; 29.7 ± 13.9 mg/L and 11.6 ± 7.7 mg/L, respectively). However, upon multivariate logistic regression analysis, these differences did not remain statistically significant. Grouping the infants of OTA-positive mothers into those who had OTA in serum above and below 2 ng/mL, showed that the former group had higher urinary levels of β 2-microglobulin (mean, SD; 322 ± 188.9 μ g/mL and 196 ± 107.9 μ g/mL, respectively) and of microalbumin (mean, SD; 37.7 ± 12.9 mg/L and 22.5 ± 10.7 mg/L). Using multivariate logistic regression analyses, the authors found a significant positive association between infant serum level of OTA and the degree of microalbuminuria, but not β 2-microglobulinuria.

The CONTAM Panel notes that in this study, albumin and β 2-microglobulin were determined in 'freshly collected' urine samples of the infants indicating that these were spot samples. Microalbuminuria, indicative of leaky kidney filtration, is defined as an albumin excretion between 30 and 300 mg/24h, or in spot samples between 30 and 300 mg/L. The reference values for β 2-microglobulin, indicative of tubular kidney dysfunction, are commonly given as $< 200\text{--}300$ μ g/L in urine, which is in the range of 10^{-3} of the values given in this study, the μ g/mL range, possibly being a misprint.

4.2.6.4. Cancer

In a study on bladder cancer patients from Pakistan, OTA concentrations in plasma were compared with levels in healthy controls (Aslam et al., 2012). Ninety-six bladder cancer cases and 31 controls were recruited. There were no differences between the groups. The mean and SD OTA concentrations in plasma of the cases and the controls were 0.33 ± 0.42 ng/mL (range: 0.03–3.41 ng/mL) and 0.31 ± 0.29 ng/mL plasma (range: 0.04–1.24 ng/mL), respectively.

The association between OTA and bladder cancer was also investigated in a cross-sectional study including 120 cases and 120 healthy controls from the Cote d'Ivoire (Thé et al., 2015). OTA was determined in blood samples and the mean and SD concentrations were 1.16 ± 1.85 μ g/L in the cases and 0.79 ± 1.2 μ g/L in the controls. These figures were not significantly different.

The association between exposure to OTA and hepatocellular cancer (HCC) was investigated in a cross-sectional study in Egypt (Ibrahim et al., 2013). Thirty-nine HCC cases were identified and matched by age, sex, residence and date of recruitment with 22 healthy controls. OTA was determined in sera from the participants. In the HCC group, the concentration of OTA ranged between 0.129 and 10.93 ng/mL with a mean value \pm SE of 1.11 ± 0.3 ng/mL, which was significantly higher than that of the healthy controls ranging between 0.005 and 0.50 ng/mL with a mean value \pm SE 0.201 ± 0.02 ng/mL. Odd ratio (OR) was calculated using a cut-off value for OTA of 0.207 ng/mL based on receiver operating curve¹² analysis. An increased risk for HCC upon OTA exposure, OR = 9.8 (95 pct. confidence interval: 2.91–32.98), was observed.

4.2.6.5. Other studies

In a study (Ates et al., 2011) from Turkey, 180 healthy individuals from different cities delivered morning urine samples and filled in a questionnaire about sex, age, smoking habits and alcohol and coffee consumption. OTA, malondialdehyde (MDA), 8-OH-dG and creatinine were determined in urine. OTA, MDA and 8-OH-dG were expressed relative to the amount of creatinine. Means and SD were: OTA 9.68 ± 4.21 ng/g creatinine, 8-OH-dG 2.91 ± 1.05 ng/mg creatinine, MDA 5.80 ± 3.67 nmol/mg creatinine. MDA was significantly lower in men than in women and in those below 35 years of age. There were no differences in urinary OTA and 8OH-dG between the sexes, non-smokers and smokers and coffee non-consumers and consumers. There was a significant correlation between OTA and 8-OH-dG ($r = 0.34$) and MDA ($r = 0.5$), and between MDA and 8-OH-dG ($r = 0.35$) in urine.

¹² A receiver operating characteristic curve, or ROC curve, is a graphical plot that illustrates the diagnostic ability of a binary classifier system as its discrimination threshold is varied.

4.2.6.6. Summary of human studies

With regard to the studies on CIN of unknown cause in Tunisia and OTA exposure, the CONTAM Panel considered not possible to causally link high levels of OTA exposure to this condition because of the cross-sectional nature of these studies. The findings of raised protein concentrations in urine of limited number of infants from Egypt exposed to high levels of OTA *via* their mothers (during pregnancy and lactation) need confirmation in larger controlled studies. In one cross-sectional study, OTA was associated with an increased risk of HCC; however, due to the small sample size and the study design limitations, no inferences on causality could be drawn. In two studies, OTA appeared not to be associated with bladder cancer. In one study, OTA in urine correlated with urinary 8OH-dG and MDA.

The CONTAM Panel did not identify studies in humans providing reliable biomarkers of OTA-specific effects, in particular on kidney function.

4.3. Evaluation of the mode of action of OTA

4.3.1. MoA on cellular toxicity in liver and kidney

4.3.1.1. Mechanism of induction of apoptosis and autophagy

OTA is well established as being toxic to a range of cell types *in vitro* in which apoptosis is implicated and *in vivo* the kidney proximal tubular cells are particularly sensitive due, at least in part, to the facilitated uptake. OTA is transported into the kidney by OAT1 (Tsuda et al., 1999) coded by the *SLC22A6* gene which is expressed predominantly in the kidney¹³ explaining the high specificity of OTA toxicity towards this organ. It is noted, however, that additional protein(s) in the kidney appear to have a high affinity for binding OTA (based on substrate competition data, Heussner et al. (2002)) and which may also contribute to concentration of OTA in the kidney and thus to this target organ specificity.

The association between oxidative stress and the loss of mitochondrial membrane potential associated with apoptosis produced by OTA was noted in a range of cell types *in vitro* (Bouaziz et al., 2008; Hsuuw et al., 2013; Liang et al., 2015; Wang et al., 2017). Caspase 3 activation associated with upregulation of the levels of p53 and p21 appeared responsible for apoptosis in oocytes and blastocysts treated with OTA (Huang and Chan, 2016). In contrast, p53 activation supplied a cell survival action against apoptosis produced by OTA in several kidney cell lines by suppressing pro-apoptotic JunN-terminal kinase (JNK, Li et al., 2011). It appears that OTA may also induce apoptosis independent of mitochondria since in human H9 T cells an increase of tumour necrosis factor- α (TNF α) and activation of caspase 8 also occurred (Darif et al., 2016).

Autophagy has also been implicated in human embryonic kidney (HEK293) cells treated with OTA and Nix (a selective autophagic receptor) was shown to play a critical role in this protective autophagic response (Shen et al., 2013). Endoplasmic reticulum (ER) stress was evident in the pig kidney along with decreased antioxidant capacity, increased p38 and phosphorylation of extracellular signal-regulated kinase 1/2 (ERK 1/2) and increased expression of genes involved in autophagy following treatment of pigs with OTA in the diet (Gan et al., 2017a; see Table 11). As a possible explanation for glomerulopathy, Sheu et al. (2017) found that OTA-activated nicotinamide adenine dinucleotide phosphate (NADPH) oxidase and calpain and caused an endoplasmic reticulum (ER) stress response and oxidative stress associated with apoptosis in mouse and rat glomerular mesangial cells.

4.3.1.2. The cellular proliferation response

Stimulation of cell proliferation by OTA is also evident in rodent kidney. In rats and mice, renal toxicity was associated with a dose-dependent increase in positive proliferating cell nuclear antigen (PCNA) signals in the kidneys (Rached et al., 2007; Qi et al., 2014a; Bondy et al., 2015; Zhu et al., 2016a). Taniai et al. (2014) and Mally et al. (2005a) also found evidence of stimulation of cell proliferation in the rat kidney along with increased incidence of apoptosis. The proliferative response was associated with changes in the expression of genes involved in response to DNA damage and cell cycle (Rached et al., 2007; Adler et al., 2009; Taniai et al., 2014). The sections below on cell signalling and gene expression help to understand the basis of the cell proliferative and apoptotic processes.

¹³ <https://www.proteinatlas.org/ENSG00000197901-SLC22A6/tissue>

4.3.1.3. Effects mediated by altered cell signalling

Altered cell signalling by OTA has been demonstrated in various cell types *in vitro* and *in vivo* (see Table 10). Prominent in these effects is the modulation of signalling involving nuclear factor kappa light chain enhancer of activated B cells (NF- κ B) (associated with inflammation and fibrosis) and mitogen-activated protein kinases (MAPK) specifically ERK 1/2, JNK and extracellular-regulated protein kinase 38 (p38) involved in inflammatory, apoptotic and fibrotic processes (Sauvant et al., 2005; Wang et al., 2012). Increase of *I κ B kinase* (IKK) and phosphorylation of NF κ B was evident in HEK293 cells (Raghubeer et al., 2017), but this anti-apoptotic, pro-inflammatory change was reversed as the concentration of OTA increased such that pro-apoptotic signals became evident. In gastric human epithelial (GES-1) cells, apoptosis and G2 phase arrest caused by OTA appears to involve Cdc25C, Cdc2 and cyclin B1 (Cui et al., 2010).

Table 10: Modulation of cell signalling by OTA

Test system	Cellular signalling system activated	Associated changes	Reference
Fischer 344 rats; 300 μ g OTA/kg bw per day; Kidney analyses	Phosphorylation of atypical PKC; ERK 1/2; ELK12 (nuclear substrate); ribosomal-S kinase (cytosolic substrate)	Authors proposed a role in stress response and cell proliferation	Mantle et al. (2005)
Rat, 300 then reduced to 100 μ g/ kg bw/day; up to 12 months	MAPK-ERK via phosphorylation of atypical PKC	Authors highlighted the roles of the altered signalling in the processes of cell proliferation, apoptosis, cell survival and potentially carcinogenesis	Marin-Kuan et al. (2007)
Mouse skin; 80 mg/ mouse; 12–72h	ERK1/2; p38 and JNK MAPK; nuclear translocation of Nrf2	Oxidative stress, Cell cycle arrest and apoptosis	Kumar et al. (2011)
Pig; Kidney analysed	p38; ERK 1/2	ER stress, decreased antioxidant capacity	Gan et al. (2017c)
Rat kidney proximal tubule cells (NRK-52E)	NF κ B; ERK 1/2; JNK and p38 (MAPK)	Apoptosis	Sauvant et al. (2005)
Human proximal tubule cells	NF κ B; collagen III; fibronectin	Hypertrophy	Schwerdt et al. (2007)
Gastric human epithelial cells (GES-1)	Cdc25C; cdc2; cyclinB1	Apoptosis and G2 phase arrest	Cui et al. (2010)
Different kidney cell lines	p53 (and associated suppression of pro-apoptosis JNK	Decreased apoptosis	Li et al. (2011)
Gastric human epithelial cells (GES-1)	ERK; p38 (MAPK)	G2 arrest	Wang et al. (2012)
Primary mouse keratinocytes	EGFR and downstream MAPKs and Akt pathways	Cell proliferation	Kumar et al. (2013)
Human proximal tubule cells (HK)	Deliberate experimental chemical inhibition of ERK 1/2	Decreased apoptosis	Özcan et al. (2015)
Oocyte and blastocyst cells	Caspase 3; p53; p21	Apoptosis	Huang and Chan (2016)
Human H9T cells	TNF α ; Caspase 8	Apoptosis	Darif et al. (2016)
PK15 cells	p38	Apoptosis	Gan et al. (2016)
Porcine primary splenocytes	ERK	Apoptosis	Gan et al. (2017b)
Rat and mouse glomerular mesangial cells	NADPH oxidase; calpain	ER stress, oxidative stress, Apoptosis	Sheu et al. (2017)

Test system	Cellular signalling system activated	Associated changes	Reference
HEK293 cells	Anti-apoptotic signalling (IKK and phosphorylation of NFκB) (Pro-apoptotic as the OTA concentration increased)		Raghubeer et al. (2017)
Rat kidney proximal tubule cells (HKC)	p53, p21, p16-pRB pathways	Senescence phenotype associated with cell cycle arrest	Yang et al. (2017)

Akt: protein kinase B; Cdc: cell division cycle; ERK: extracellular signal regulated kinase; EGFR: epidermal growth factor receptor; ELK: ETS domain containing protein; ETS: E26 transformation specific; ER: Endoplasmatic reticulum; G2: gap 2 phase; IGF: insulin-like growth factor; IKK: Iκβ kinase; JNK: c-Jun N-terminal kinase; MAPK: mitogen-activated protein kinase; NADPH: nicotinamide adenine dinucleotide phosphate; NfκB: Nuclear factor κB; Nrf2: nuclear factor erythroid 2-related factor 2; p16, p21, p38, p53; extracellular-regulated protein kinase p16, p21, p38, p53; PDK: Phosphoinositide-dependent kinase; PKC: protein kinase C.

Further studies *in vivo* focused on interference of signal transduction in the kidneys of Fischer 344 rats given OTA in the diet at 300 µg/kg bw per day (Mantle et al., 2005). There was an increase in the phosphorylation of atypical protein kinase C (PKC) and a downstream activation of ERK1/2 and of their nuclear substrate ETS-domain protein 1 (ELK 1/2) and cytosolic substrate, ribosomal-S6 kinase (p90RSK). PKC activation appeared to be due to mobilisation of the insulin-like growth factor-1 receptor (IGF1R) and phosphoinositide-dependent kinase-1 system (PDK1). The authors considered that signal transduction modulation may be involved in stimulation of a stress response and cell proliferation. MAPK-ERK activation, via phosphorylation of atypical protein kinase C, was also evident in the kidneys of rats fed OTA (Marin-Kuan et al., 2007). The roles of PKC and MAPK pathways in cell proliferation, apoptosis, cell survival and potentially carcinogenesis were highlighted.

4.3.1.4. Alteration of gene expression

Various studies have investigated altered gene expression induced by OTA. These findings relating to kidney or liver both *in vitro* and *in vivo* are summarised in Table 11 along with changes in microRNA and proteomic profiles. Prominent in these findings are changes in the expression of genes involved in inflammation, fibrosis, malignant transformation and epithelial to mesenchymal transition. In HepG2 cells, enhanced expression of genes related to inflammation, oxidative stress, cell pro-survival, energy and xenobiotic metabolism was observed (Hundhausen et al., 2008). A set of OTA-inducible genes was detected using transcriptomic analyses in human and rat renal proximal tubular cells. Major biological processes implicated were related to cytoskeleton, nucleosome regulation, translation, transcription, ubiquitination and cell cycle. Surprisingly, the oxidative stress nuclear factor-erythroid 2 p45-related factor (Nrf2) pathway was not affected in this study (Jennings et al., 2012).

Important *in vivo* studies showed that, in rats treated with OTA, the degree of differentially expressed genes was greater in kidney than in liver. Genes involved in oxidative stress, calcium homeostasis, metabolism and transport were prominent in downregulation whereas genes involved in cell survival and proliferation were elevated in expression (Arbillaga et al., 2008). In further transcriptomic analyses, rats were given OTA in the feed (Marin-Kuan et al., 2006; see Section 3.2.2). Gene expression was assessed in kidney and liver at 7 days and at 12 months. There was little evidence of a DNA damage response with the most prominent changes in gene expression being kidney transcription factors hepatocyte nuclear factor 4α (HNF4α) and Nrf2 and genes regulated by these factors suggesting impairment of defence mechanisms. A strong downregulation of regucalcin was seen. Regucalcin is involved in the intracellular calcium homeostasis in kidney tubule cells. Downregulation of Nrf2 gene expression paralleled by induction of DNA damage measured as formation of abasic DNA sites was observed both in kidney NRK cells and *in vivo* (Cavin et al., 2007). Based on these results, the authors proposed that the loss of Nrf2 protection against oxidative stress may play an important role in kidney toxicity and carcinogenesis. Indeed, pretreatment of primary isolated rat hepatocytes with activators of Nrf2 reduced oxidative stress, protein nitration and cytotoxicity induced by OTA (Cavin et al., 2009). When Nrf2 was lacking in porcine or mouse kidney tubular epithelial cells and in mice *in vivo*, this exacerbated OTA-induced toxicity (Loboda et al., 2017a). Haem oxygenase (HO-1) induction by cobalt protoporphyrin attenuated the nephrotoxic effect of OTA in mice and HO-1-deficient mice were more sensitive (Loboda et al., 2017b). Moreover, Stachurska et al. (2013) showed that OTA attenuates Nrf2 and HO-1 via induction of microRNAs

(miR-132 and miR-200c) that contributes to elevation of ROS and pro-fibrotic TGF β expression in porcine renal proximal tubule cells.

Microarray analyses were also carried out in kidney samples taken from pigs given OTA in the feed (Marin et al., 2017a). Assessment of biological function of altered gene expressions indicated changes relating to immune response, oxidative stress and the growth, proliferation, death and survival of cells. Alterations in gene expression in the kidney in which there was OTA-induced toxicity have also been associated with transcriptional changes in genes involved in DNA damage response and apoptosis, response to oxidative stress and inflammatory reactions (Arbillaga et al., 2008; Jennings et al., 2012).

OTA has also been found to modulate the expression of microRNAs, particularly in kidney cells *in vivo* and *in vitro* (see Table 11). Many of the altered miRNAs are involved in the MAPK signalling pathways, in support of the signalling changes summarised above, but of particular interest was the suppression of miRNAs involved in the production of microRNAs themselves which could have implications for toxicity. The microRNA MiR-122 was involved in the induction of apoptosis (Chen et al., 2015; Zhu et al., 2016b).

Proteomic approaches have also been used to assess factors involved in OTA toxicity (see Table 11). Notable are the enhanced expression of mitochondrial proteins involved in electron transport, protein synthesis, stress response and cell death and modulation of proteins involved in inflammation (Ferrante et al., 2006; Shen et al., 2013). Qi et al. (2014b) provided a comprehensive analysis of molecular changes in liver based on profiling of microRNAs, mRNAs and proteins following treatment of rats with OTA by gavage. The combined analyses provided evidence of five predominant pathways that were modulated (thiol metabolism, PPAR signalling, bile acid synthesis, arginine and proline metabolism and xenobiotic metabolism) indicative of liver toxicity and metabolic disease.

Table 11: Effect of OTA on the expression of genes and microRNAs and associated proteomic analyses relevant to the kidney and liver

Test system	Methodology employed	Modulation observed	Associated changes or observations	Reference
Mouse, 10 mg OTA/kg bw, single dose; after 24 h kidney was analysed	Proteomic analyses	Modulation of proteins in peritoneal macrophages involved in inflammation	Associated with kidney and liver toxicity	Ferrante et al. (2006)
Rat; 300 then reduced to 100 µg OTA/kg bw per day; Kidney and liver analysed after 7 days and 12 months	Transcriptomic analyses	In kidney greater degree of differentially expressed genes than in liver. Modulation of expression of genes as markers of kidney injury, cell and pathways regulated by HNF4a and Nrf2. Downregulation of regucalcin	Authors noted little evidence of a DNA-damage response or of apoptosis and concluded that the effects suggested impairment of defence mechanisms. The authors noted the role of regucalcin in the regulation of calcium homeostasis. Downregulation of Nrf2 was associated with oxidative DNA damage	Marin-Kuan et al. (2006)
Rat, 300 then reduced to 100 µg OTA/kg bw per day; Kidney analysed after 21 days and 12 months	Assessment of proteins regulated by Nrf2	Decreased protein markers regulated by Nrf2		Cavin et al. (2007)
Rat, gavaged daily with 500µg OTA/kg bw; Kidney and liver analysed at 7 and 21 days	Transcriptomic analyses	Kidney greater degree of differentially expressed genes than in liver. Downregulation of genes was the predominant effect notably for genes involved in oxidative stress, calcium homeostasis, metabolism and transport. Upregulation of genes involved in cell survival and proliferation	Kidney toxicity	Arbillaga et al. (2008)
Rat, 21, 70 and 210 µg OTA/kg bw per day for up to 90 days (kidneys analysed)	qPCR	Modulation of the expression of genes relating to chromosomal instability and control of cell cycle	Changes were associated with a proliferative response	Adler et al. (2009)
Rat, 3 mg OTA /kg per day for 1, 3 and 7 days via gavage, Analysis of kidneys and various kidney cells <i>in vitro</i>	Transcriptomic analyses	Modulation of expression of genes involved in cytoskeleton, nucleosome regulation, translation, transcription, ubiquitination and cell cycle pathways		Jennings et al. (2012)
Rat; 70 and 210 µg OTA/kg bw up to 26 weeks; Kidney analysed	MicroRNA profiling	Alteration of microRNAs involved in MAPK signalling Suppression of microRNAs involved in the production of microRNAs themselves		Dai et al. (2014)
Rat, (70 or 210 µg OTA/kg bw per day up to 26 weeks; Liver analysed	MicroRNA profiling; Transcriptomic analyses; Proteomic analyses	Modulation of thiol metabolism, PPAR signalling, bile acid synthesis, arginine and proline metabolism and xenobiotic metabolism	Authors concluded the changes were indicative of liver toxicity and metabolic disease	Qi et al. (2014b)

Test system	Methodology employed	Modulation observed	Associated changes or observations	Reference
Rat, 210 µg OTA/kg bw per day for 28 days	qPCR	Modulation of expression of genes involved in oxidative stress	Changes were associated with apoptosis, cell proliferation and disruption of cell cycle control	Taniai et al. (2014)
Human primary proximal tubule cells	qPCR	Alteration of expression of genes involved in inflammation. Malignant transformation and epithelial-to-mesenchymal transition. Notable upregulation of Wnt-1	Authors noted the role of Wnt-1 as a growth factor involved in oncogenesis and fibrosis	Hennemeier et al. (2012)
HepG2 cells	Transcriptomic analyses	Enhanced expression of genes involved in inflammation, oxidative stress, cell pro-survival, energy and xenobiotic metabolism		Hundhausen et al. (2008)

Porcine proximal tubule cells	Specific product analyses	Attenuation of Nrf2 and Haem oxygenase via induction of microRNAs (miR-132 and miR-200c) and pro-fibrotic TGFβ		Stachurska et al. (2013)
HEK293 cells	Specific product analyses	Post-transcriptional reduction of miR-29B	Collagen formation (marker of fibrosis)	Hennemeier et al. (2014)
Mouse spermatid cells (GC-2)	MicroRNA analyses	Expression of MiR-122	Caspase-3 mediated apoptosis	Chen et al. (2015)
Rat hepatocytes <i>in vitro</i> and <i>in vivo</i> and in HEPG2 cells	MicroRNA analyses	Expression of MiR-122	Apoptosis	Zhu et al. (2016b)
HepG2 and HEK293 cells also in rat; 70 and 210 µg OTA /kg bw for 13 weeks; kidney analysed	MicroRNA profiling	Deregulation of microRNAs involved in signal transduction and human cancer		Zhao et al. (2017)

HNF4a: hepatocyte nuclear factor 4 α ; MiR; microRNA; Nrf2: Nuclear factor erythroid 2-related factor 2; OTA: ochratoxin A; qPCR: quantitative polymerase chain reaction; TGFβ: tumour growth factor β; PPAR: peroxisome proliferator-activated receptor; RNA: ribonucleic acid; MMTV: mouse mammary tumour virus; Wnt-1: wingless-type MMTV integration site family, member 1, a proto-oncogene protein.

4.3.1.5. Role of oxidative stress in OTA-toxicity

The downregulation of Nrf2 (see above) is a major contributor to the induction of cellular oxidative stress induced by OTA. There is also evidence that an Fe³⁺ complex with OTA can produce hydroxyl radicals in the presence of NADPH and NADPH-cytochrome-P-450 reductase (Hasinoff et al., 1990). Evidence for oxidative DNA damage in rat kidney and in liver has been noted (Kamp et al., 2005; Mally et al., 2005a) although oxidative stress in the rat kidney was only minimal in the study by Zhu et al. (2016a). In cultured porcine kidney tubule cells (LLC-PK1), OTA decreased superoxide dismutase, elevated reactive oxygen species and downregulated expression of glutathione S-transferase (GST) associated with a lowered activation of Nrf-2 (Bösch-Saadatmandi et al., 2008, 2009). The ratio of glutathione (GSH)/glutathione disulfide (GSSG) was reduced as were total thiols and heat shock proteins were downregulated in PK15 porcine kidney cells treated with OTA (Klarić et al., 2014). Oxidative stress is also evidenced in pigs and in rats by altered activity of superoxide dismutase (SOD), increased protein carbonyls and modulation of the expression of genes involved in response to oxidative stress (Domijan et al., 2006; Zhang et al., 2016) along with downregulation of gene expression of markers of inflammation (interleukin (IL)-6, IL-8, IL-12, IL-17A, IL-18 –colon; IL-17A and IL-10-kidney). These effects correlated with renal toxicity and the modulation of the expression of genes functionally associated with renal necrosis, kidney failure, renal proliferation, renal dysplasia and hypoplasia (Marin et al., 2017a,b). In support of the evidence for oxidative stress in playing a role in OTA adverse effects, protection is afforded by antioxidants and scavengers of free radicals. See Tables B.1 and B.2 of Appendix B.

4.3.1.6. Summary of OTA – induced cell toxicity via modulation of gene expression and cell signalling

In summary, OTA causes cell death in a wide range of cell types both *in vitro* and *in vivo*. Both mitochondrial/caspase 3 and caspase 8-mediated apoptotic pathways have been implicated. The kidney proximal tubule cells are particularly sensitive due to the presence of anion transport systems for uptake. OTA alters the expression of proteins via transcriptional, microRNA and protein post-translational modifications to modulate cell signalling systems responsible for apoptosis and also pathways related to stress responses, inflammation, fibrosis and the balance between cell survival, cell proliferation, cell division and cell death. Activation of PKC and MAPK-ERK signalling pathways play an important role in the stress response and cell proliferation. Particularly important is the downregulation of Nrf2 which contributes to the oxidative stress induced by OTA (see below).

4.3.1.7. Potential for toxicity in cell types other than those in the kidney and liver

4.3.1.7.1. Immune system

There is evidence mainly from *in vitro* studies, for effects of OTA on neutrophils and macrophages including oxidative stress, apoptosis, phosphorylation of the ERK1/2 and release of TNF α via NF- κ B pathways by OTA (Al-Anati et al., 2010; Liu et al., 2012; Giromini et al., 2016; Kupski et al., 2016; Brennan et al., 2017; Xu et al., 2017). Further observations in human blood mononuclear cells (Rossiello et al., 2008) indicated that OTA reduced the ability of lipopolysaccharide, phorbol myristate, IL-1 β or TNF α to produce tissue factor and plasminogen activator inhibitor 2 which led the authors to propose a MoA in immunosuppression. Although Ferrante et al. (2006) found infiltration of polymorphonuclear infiltration into the duodenum following a single dose of OTA in mice, the role of the immune response towards oxidative stress in the kidney *in vivo* has not been demonstrated.

4.3.1.7.2. Intestine

The ability of OTA to affect intestinal function has also been assessed *in vitro* using Caco-2 cells, porcine intestinal epithelial (IPEC-J2) cells or mouse rectal CMT93-II cells. OTA disrupted barrier dysfunction through reduction of claudins (Lambert et al., 2007; Maresca et al., 2008; Romero et al., 2016; Nakayama et al., 2018; Wang et al., 2018). The significance of these finding *in vivo* is yet to be established.

4.3.1.7.3. Nervous system

Neurological toxicity of OTA during embryonic development has been noted above (see Section 4.2.5 on Reproductive toxicity). Following treatment of mice with OTA behavioural studies showed adversity resembling Parkinsonian features which were ameliorated with L-Dopa (Bhat et al., 2018). Oxidative stress and inflammation produced by OTA are associated with neuronal toxicity

in vitro and *in vivo* (Sava et al., 2006; Bang et al., 2009; Yoon et al., 2009; Zhang et al., 2009; Razafimanjato et al., 2010; Bhat et al., 2016) also found that OTA could inhibit glutamate uptake by rat astrocytes but the relevance *in vivo* is uncertain.

4.3.1.7.4. Endocrine systems

OTA was found not to interact with steroid receptors, but in H295R cells, it increased production of oestradiol and increased the aromatase protein at 1 $\mu\text{mol/mL}$ (Frizzell et al., 2013). Furthermore, Woo et al. (2013) reported that OTA upregulated 3 β -hydroxysteroid dehydrogenase/isomerase expression and there was an associated increase in progesterone secretion in human placental JEG-3 cells. Kumar et al. (2011) found alteration of the blood levels of a range of hormones (triiodothyronine, thyroxine, testosterone, insulin, prolactin and cortisol) following dosage of OTA in the feed of rats for 30 days, but the mechanisms of these changes were not clear.

4.3.2. Mode of action in carcinogenesis

The results of genotoxicity tests with OTA are provided in Section 4.2.4 on Genotoxicity. A key question concerns the ability of OTA, or a metabolite, to form DNA adducts which could be responsible for the DNA damage and mutational spectra observed in rodent kidney. The weight of evidence suggests that metabolic activation of OTA to a reactive metabolite does not occur (see Section 4.1.1 on Toxicokinetics). Evidence for the formation of OTA-derived DNA adducts in the kidney outer medulla site of carcinogenicity is controversial (see Section 4.2.2 on Repeated dose studies for details of studies). Whereas P³²-post-labelling studies have suggested the presence of DNA adducts (albeit uncharacterised), other studies using accelerator mass spectrometry or isotope dilution have failed to detect such adducts. Thus, DNA adducts are either not produced from OTA at all or (at most) the level of adducts is extremely low (no more than 10 adducts/cell).

OTA induces gene mutations in rats and mice only in the outer medulla of the kidney and only at the *Red/Gam* locus (*Spi*-mutants), which has been specifically devised to detect deletion mutations (Hibi et al., 2011; Kuroda et al., 2014). Hibi et al. (2013b) found altered expression of genes involved in the DNA damage response and cell cycle regulation in the outer medulla of rats following dietary administration of OTA for 4 weeks. The authors considered the pattern of altered gene expression as evidence of DNA DSBs. Indeed, large deletion mutations and DSBs were found in rat kidney associated with increased γ -H2AX protein expression and increased expression of homologous recombination repair-related genes and genes involved in cell cycle arrest following administration of OTA by gavage for 4 weeks to rats (Kuroda et al., 2014, 2015).

In an attempt to understand the occurrence of *Spi*⁻ mutations in the kidneys of p53-deficient *Gpt* mice (but not in p53-proficient mice), Kuroda et al. (2015) considered that homologous recombination repair was responsible for the single base mutations seen in the absence of p53 since only in the presence of p53 did DNA DSBs arise. Importantly, Bondy et al. (2015) found no increased sensitivity to OTA tumourigenicity as a result of p53 heterozygosity in mice following administration in the diet for 26 weeks. The authors considered this as evidence of a non-genotoxic MoA. Bloch et al. (2012) attempted to distinguish between genotoxic and non-genotoxic renal carcinogens based on their profile of alteration of gene expression in NRK-52E cells, using OTA to represent the non-genotoxic class of carcinogen. However, several pathways were common to both genotoxic and non-genotoxic categories making distinction not possible. The production of a senescence phenotype associated with cell cycle arrest was detected in rat kidney proximal tubular cells (HKC) exposed to OTA and this was associated with activation of the p53-p21 and p16-pRB pathways (Yang et al., 2017). Disturbance of mitosis and chromosomal segregation appear to be important (Mosesso et al., 2008; Czakai et al., 2011). The processes involved in DNA damage following disturbance of the cell cycle and cytokinesis are discussed in detail by Hayashi and Karlseder (2013) and by Bizard and Hickson (2018). It is possible that the mutations arise as a result of the evident replication stress as discussed by Gelot et al. (2015). The mechanism leading to replicative stress is, however, unclear.

In immortalised human kidney epithelial cells exposed to OTA, increases in apoptosis and decreases in the rate of mitosis were associated with an increase in aberrant mitotic figures with misaligned chromosomes and formation of giant cells with abnormally large or multiple nuclei. The authors concluded that OTA might promote tumour formation via interference with microtubule dynamics and mitotic spindle formation, resulting in apoptosis or interruption of mitosis to explain the observed cytogenetic abnormalities. A cell-free *in vitro* tubulin polymerisation assay showed that OTA inhibited microtubule assembly (Rached et al., 2006). However, the mechanism is unclear and the inhibitory

concentration of OTA was relatively high. Similar effects have been observed with citrinin, another mycotoxin (Pfeiffer et al., 1998).

Nuclear enlargement was also seen in kidney proximal tubule cells in OTA-treated F344 rats (Rached et al., 2007). Moreover, in rats, mRNA levels for various regulators of mitosis and genes linked to chromosomal instability were over-expressed in kidney of OTA-treated rats, whereas Cx32 and regucalcin genes were downregulated (Adler et al., 2009). The authors suggest that aberrant mitosis may play a role in kidney carcinogenesis. However, the Panel notes that the gene expression changes could potentially be causative or a consequence of carcinogenesis. OTA can interfere with DNA topoisomerase II and chromosome segregation during cell division (Cosimi et al., 2009) and disruption of chromosome separation and progression of mitosis as a non-DNA reactive mechanism was also proposed by Mosesso et al. (2008) as evidenced by detection of endoreduplication and chromatid separation in V79 cells.

In conclusion, post-translational modification of proteins and the alteration of gene expression detailed above may contribute to modulation of the cell cycle and spindle function leading to aberrant alignment of chromosomes, increased ploidy and karyomegaly. In association with the cell proliferative responses and the effect on DNA repair enzymes described above, these changes appear to lead to genomic instability. The processes involved in DNA damage may follow disturbance of the cell cycle and cytokinesis.

4.3.2.1. The contribution of additional non-DNA reactive mechanisms

4.3.2.1.1. Secondary oxidative genotoxicity

The question arises as to whether DNA damage may result from secondary production of ROS (see above). In several cellular systems *in vitro* the ability of DNA repair enzymes (formamido-pyrimidine-DNA glycosylase (Fpg) or endonuclease III) used in the Comet assay to convert oxidative DNA damage into SSBs was shown. This provided evidence of DNA oxidation (Kamp et al., 2005; Arbillaga et al., 2007; Ali et al., 2014). However, despite oxidative stress under these conditions, there was no change in the expression of genes involved in a DNA damage response (DNA repair, apoptosis and cell cycle control; Arbillaga et al., 2007). Similar evidence for oxidative DNA damage comes from some studies on SSBs (Comet assay) observed in cells derived from liver and kidney of Fischer rats treated with OTA (Mally et al., 2005b; Domijan et al., 2006). However, the major oxidised base 8-OHdG was not detected *in vivo* in rat kidney (Mally et al., 2005a, 2005b) and GC:TA transversions (typically associated with DNA oxidation) were not seen in rats treated with OTA (Hibi et al., 2011).

Kumar et al. (2012) assessed tumour formation in mouse skin. A single topical application of OTA (80 mg/mouse) followed by twice weekly application of the tumour promoting agent 12-Otetradecanoylphorbol-13-acetate for 24 weeks lead to tumour formation. The authors associated this effect to the evident oxidative stress, MAPKs signalling and DNA damage.

4.3.2.1.2. Altered cell signalling and cell proliferation

Cell proliferation in the kidney of rats given OTA was considered by Qi et al. (2014a) to be a major factor in kidney carcinogenesis. They found that, in association with kidney toxicity, there was a dose-related increase seen in proliferating cell nuclear antigen (PCNA). p53 gene expression was also decreased in both kidney and liver. Abassi et al. (2016) found that OTA-induced clonogenicity in human colon carcinoma cells and fetal lung fibroblast-like cells transformed with MYC. In an attempt to understand the apparent tumour promoting action of OTA on mouse skin, primary murine keratinocytes were treated with OTA which was found to cause cell proliferation and activation of EGFR and downstream MAPKs and Akt pathways (Kumar et al., 2013). Further evidence of the importance of proliferative changes in rat kidney carcinogenesis come from the observation that OTA activated Topo II α , Ubd and apoptosis that cooperate in inducing a marked proliferative response (Taniai et al., 2012a). In this study, proximal tubule cell proliferation was accompanied by increased levels of topoisomerase II α protein and evidence of DNA damage and cell cycle disruption (G₂M transition) (Taniai et al., 2012b). Using the same treatment regime, karyomegaly and aberrations of the cell cycle were seen in the kidney tubular cells without evidence of oxidative stress (Taniai et al., 2014).

4.3.2.1.3. Effect on intercellular communication

Many non-genotoxic carcinogens interfere with connexin-mediated intercellular communication (e.g. Chipman et al., 2003). The ability of OTA to inhibit gap junctional intercellular communication was studied in Madin Darby canine kidney (MDCK) cells (Mally et al., 2006). In the absence of cytotoxicity, there was a significant reduction of intercellular communication which was associated with a small, but

dose-dependent, decrease in the concentration of the gap junction protein connexin 43. Adler et al. (2009) found that there was a downregulation of Cx32 in rat kidney following 90-day treatment with OTA. In the liver of rats given OTA (289 µg/kg bw alternate days for 90 days), there was a reduction of E-cadherin and the connexins 26, 32 and 43 implying interference with intercellular gap junctional communication (Gagliano et al., 2006).

4.3.2.1.4. Epigenetic mechanisms

Various studies in cell cultures have demonstrated modulation of histone acetylation (Czakai et al., 2011; Giromini et al., 2016; Limbeck et al., 2018). In Fischer 344 rats given OTA in the diet at 300 µg/kg bw per day (Mantle et al., 2005) an increased histone deacetylase (HDAC) enzymatic activity associated with enhanced HDAC3 protein levels was measured which may give rise to epigenetic modulation (Oh et al., 2013). Genome wide analysis of DNA methylation in rat kidney following treatment of rats with OTA (210 µg/kg by gavage 5 days/week for 90 days) revealed that various categories of genes were either hypermethylated or hypomethylated including those involved in protein kinase activity and mTOR cell signalling (Ozden et al., 2015). Li et al. (2015) gave rats 70 or 210 µg/kg body weight OTA by gavage for up to 26 weeks and measured parameters relating to DNA methylation in the kidney. Dynamic and dose-dependent alteration of global DNA methylation was seen in this study with hypermethylation of the promoters of E-cadherin and N-cadherin (along with reduced expression) and increased expression of Wnt and P13K/AKT pathways.

4.3.2.2. Overall conclusion on the MoA in carcinogenesis

Non-genotoxic mechanisms appear to contribute to carcinogenesis. This is based on a stress response (including an oxidative stress) involving alteration of gene expression (in part mediated by epigenetic modifications) contributing to modulation of DNA repair enzymes, disruption of cell cycle and an imbalance of apoptosis and cell proliferation. Spindle function is impaired leading to aberrant alignment of chromosomes. There is increased ploidy, aneuploidy and karyomegaly. In combination, these effects appear to lead to genomic instability and large deletions of DNA in surviving proliferating cells. The precise mechanism whereby OTA leads to the observed low level of mutations at the target site in rat kidney remains unclear. The mutational spectrum is not consistent with reactive oxygen damage. One possibility is through interaction of OTA with DNA, although the evidence for DNA adducts is weak. A further possibility is that the mutations arise as a result of the evident replication stress. In that event, there remains uncertainty also as to the cause of the replication stress which may result both from initial DNA damage (direct or secondary to oxidation) or from modulation of proteins that regulate the cell cycle including those coded by oncogenes. In conclusion, there is insufficient evidence to support either direct DNA damage or indirect DNA damage in OTA carcinogenesis.

4.4. Identification of critical effects

4.4.1. Identification of critical acute effects

The evidence of acute effects of OTA in laboratory animals is very limited and no relevant studies published since the last EFSA assessment in 2006 has been identified (see Section 4.2.1 on Acute toxicity). No acute effects upon exposure to OTA in humans have been reported (see Section 4.2.6 on Observations in humans). Thus, the CONTAM Panel concluded that acute toxicity is not a critical effect for the hazard assessment of OTA.

4.4.2. Identification of critical chronic effects

In the previous OTA opinion (EFSA, 2006), the CONTAM Panel concluded that the kidney is the main target organ for the adverse effects of OTA and that immunotoxic, neurotoxic and teratogenic effects were observed at high dose levels. OTA has been shown to induce nephrotoxicity in mice, rats, dogs and pigs. Long-term administration of OTA caused renal tumours in rats and mice and a NOAEL/LOAEL of 15/50 µg/kg bw per day (extrapolated from the doses from 5 days treatment per week) for tumour induction was derived from a 2-year gavage study with Fischer 344/N rats (NTP, 1989). The mechanisms underlying the genotoxicity associated with OTA exposure were unclear and the Panel was unable to conclude whether OTA causes DNA damage by indirect or direct effects. Epidemiological studies were insufficient to classify OTA as renal carcinogen or link it to BEN or other endemic nephropathies of unknown cause. Considering a series of repeated dose studies in female pigs, the Panel identified a LOAEL of 8 µg/kg bw per day from a 90-day feeding study with pigs for minimal

morphological changes in kidney, changes in renal enzymes and impaired renal function (Krogh et al., 1974) as critical for the setting of a chronic HBGV (i.e. a TWI).

For the present opinion, the pivotal studies in pigs used as a basis to establish a HBGV previously have been re-evaluated. In addition, new *in vivo* toxicity studies with mice, rats, rabbits and pigs published since the 2006 opinion of EFSA were reviewed to identify if any studies would provide observations of adverse effects lower than the LOAEL of 8 µg/kg bw per day previously identified in pigs (EFSA, 2006). Additionally, human evidence published since 2006 was also considered.

The new repeated doses studies are described in detail in Section 4.2 on Toxicity. In brief, the new subacute/subchronic studies with rats were mainly designed to elucidate the mechanism of OTA induced nephrotoxicity and thus employed dose levels known to be toxic. None of these studies provided observations of adverse effects lower than the LOAEL of 15 µg/kg bw derived from the 90-day feeding study in Wistar rats from Munro et al. (1974). In new repeated dose studies with rabbits, liver and kidney toxicity was reported in rabbits, albeit not at doses as low as the LOAELs of 15 and 8 µg/kg bw previously identified in subchronic/subacute studies with rats and pigs, respectively (FAO/WHO, 2001; EFSA, 2006). The results of the new subacute/subchronic dose toxicity studies in mice are consistent with the lower sensitivity of mice to OTA toxicity as compared to rats and pigs. Likewise, none of the new studies provided observations to suggest NOAELs/LOAELs lower than the LOAELs of 15 and 8 µg/kg bw previously identified in rats and pigs, respectively (FAO/WHO, 2001; EFSA, 2006). Overall, the CONTAM Panel concluded that the new studies in pigs, even though most of them are of shorter duration, support OTA-mediated adverse effects at dose levels close to the previously established LOAEL of 8 µg/kg bw per day.

The CONTAM Panel noted that the new chronic studies with rats were inadequate for risk assessment based on their study design. The new evidence on possible toxicity in humans is described in detail in Section 4.2.6 Observations in humans. The CONTAM Panel concluded that it is not possible to establish a causal link of exposure to OTA and adverse effects observed in epidemiological studies in humans.

Based on the above, the CONTAM Panel concluded that the results obtained in the 3-month study in female pigs (Krogh et al., 1974) and in which an LOAEL of 8 µg/kg bw per day had been previously established were the most relevant for assessment of non-neoplastic chronic health hazards (for details on the study see Appendix C.2). The CONTAM Panel considered the increase in total incidence of microscopic kidney lesions and the microscopic tubular lesions in the kidney occurring in 45% of the pigs at 8 µg/kg bw per day as the most appropriate endpoint for characterisation of non-neoplastic hazards.

The CONTAM Panel also considered an increased percentage of glucose excretion as a potential critical effect for the characterisation of non-neoplastic hazards. However, the CONTAM Panel noted the big standard deviations in all treated groups as well as in the control presented a large uncertainty and limited the use of this endpoint for BMD analysis. Furthermore, it was not possible to identify a biologically relevant BMR for this endpoint. Nevertheless, the observed effects on glucose, indicative of impaired tubular reabsorption of glucose, give supportive evidence for the use of microscopic kidney lesion for assessment of non-neoplastic hazards. In a previous evaluation reduced p-aminohippuric acid renal transport maximum (T_{mPAH}) (reduced maximum tubular excretion of PAH) observed in the same experiment on pigs (Krogh et al., 1974) was used as a reference point for hazard characterisation (FAO/WHO, 2008). However, as OTA and PAH use the same transporters, OATs, in the renal tubular cells, this effect might have been the result of competitive inhibition rather than a toxic response.

The mode of action for OTA-induced carcinogenesis is described in detail in Section 4.3.2 on Mode of action. OTA causes kidney tumours in mice and rats, the male rat being most sensitive (NTP, 1989). There is a large, but inconsistent database on possible direct and indirect interactions of OTA with DNA including also many recent experiments.

Following respective EFSA guidance documents (EFSA, 2005; EFSA Scientific Committee, 2012a), the CONTAM Panel concluded that the kidney tumours occurring in male rats (at much higher dose than the non-neoplastic effects seen in kidney in pigs or rats) are of relevance for the risk characterisation of the compound. There is insufficient evidence to rule out that direct DNA damage contributes to their formation. The kidney tumours observed in male rats in a 2-year feeding study (NTP, 1989) were considered as critical and thus to be used for characterisation of neoplastic hazard characterisation of OTA.

4.5. Calculation of benchmark doses

The benchmark dose (BMD) analyses were performed following the guidance of the Scientific Committee on BMD modelling (EFSA Scientific Committee, 2017).

4.5.1. Non-neoplastic endpoints

For microscopic kidney lesions seen in the study of Krogh et al. (1974) using a standard benchmark response (BMR) of 10% for quantal data, a BMD confidence interval (BMDL₁₀–BMDU₁₀) of 4.73–7.17 µg OTA/kg bw per day was calculated. A detailed description of the BMD analysis can be found in Appendix F.1.

4.5.2. Neoplastic endpoints

Using the standard BMR of 10% for quantal data a BMD (BMDL₁₀–BMDU₁₀) of 14.5–36 µg OTA/kg bw per day for the combined incidences of adenoma and carcinoma in male rats seen in a 2-year oral study (NTP, 1989) was calculated and used for the neoplastic risk characterisation. A detailed description of the BMD analysis can be found in Appendix F.2.

4.5.3. Consideration of toxicokinetic differences between species

As described in Section 2.2 on Previous assessments, in the EFSA assessment of 2006, an UF of 6 for toxicokinetic interspecies variability instead of the default value of 4 was applied for derivation of a TWI because of the longer half-life of humans as compared to pigs. However, as discussed in the present opinion in Section 3.1 on Toxicokinetics, OTA exhibits very high non-covalent binding to plasma proteins, in particular albumin, in laboratory animals and humans. In general, only the free (unbound) proportion of a substance present in blood plasma undergoes glomerular filtration in the kidneys. Therefore, high plasma protein binding (PPB) decreases the elimination of compounds from blood plasma and leads to increases in plasma half-lives and, after repeated exposure, to accumulation. Due to differences in the extent of PPB between species, the proportion of free OTA in the blood and the accumulation of OTA differ markedly between humans and experimental animals.

According to the different affinity constants for PPB in humans, pigs and rats, and assuming the same total OTA concentration (bound plus unbound) in blood, it has been calculated (see Appendix D) that the plasma concentration of free OTA is about 70-fold lower in humans than in pigs, and about 120-fold lower in humans than in rats. On the other hand, if humans (with a plasma half-life of 35 days), pigs (5–6 days) and rats (5–6 days) are exposed to the same level of OTA in their diet and the total plasma concentration of OTA at steady state will be about six times higher in humans than in pigs and about six times higher in humans than in rats. This assumes the same bioavailability and rate of metabolism in each species. Taking into account both the accumulation and the PPB at equal exposure (same external dose), the plasma levels of free OTA in humans should still be about 10 times lower in humans than in pigs and 18 times lower in humans than in rats. Therefore, the CONTAM Panel considered that an extra UF factor for accumulation in humans is not necessary and the default factor of 4 is sufficient to account for toxicokinetic interspecies differences.

4.6. Establishment of a health-based guidance value (HBGV) vs. application of a margin of exposure (MOE) approach

As described in Section 4.4 on Identification of critical effects, the CONTAM Panel concluded that there is clear evidence for carcinogenic effects of OTA. The mechanisms underlying the genotoxicity associated with OTA exposure are unclear and the Panel was unable to conclude whether OTA causes DNA damage by indirect or direct effects. Following respective EFSA guidance on substances that are both genotoxic and carcinogenic (EFSA, 2005; EFSA Scientific Committee, 2012a), the CONTAM Panel considered it was not appropriate to establish a tolerable daily intake (TDI) or a TWI and concluded that for both non-neoplastic and neoplastic effects of OTA an MOE approach needs to be applied for risk characterisation. As a consequence, the TWI of 120 ng OTA/kg bw as established by the CONTAM Panel in 2006 is no longer valid.

The increased incidence of microscopic kidney lesions seen in a 3-month feeding study with pigs (Krogh et al., 1974) was considered as the most appropriate endpoint of non-neoplastic effects of OTA and the resulting BMDL of 4.73 µg/kg bw per day was used for comparison with chronic exposures. The CONTAM Panel concluded, that an MOE of 200 needs to be applied to this BMDL consisting of the

default UFs of 100 for toxicodynamic and toxicokinetic inter- and intraspecies differences and an additional UF of 2 considering the short study duration of Krogh et al. (1974) (3 months) that does not cover the entire lifespan of the animals (pigs) tested. In this context, it needs to be noted that in the previous EFSA opinion (EFSA, 2006) for derivation of a TWI, a specific UF of 6 for toxicokinetic differences between pigs and humans (instead of the default 4) was introduced because of the longer half-life of OTA in humans (see Section 2.2 on Previous risk assessments). Upon a comprehensive re-evaluation of the toxicokinetic data of OTA in different species including OTA plasma protein binding, the CONTAM Panel concluded that such additional UF is not needed (for details see Section 4.1.1 on Toxicokinetics).

The EFSA guidance on default values (EFSA Scientific Committee, 2012a) issued after publication of the previous EFSA opinion on OTA (EFSA, 2006) proposes the use of an UF of 2 for extrapolation from subchronic to chronic duration in rodents. The CONTAM Panel noted that no differences were observed between NOAELs derived from subacute, subchronic and chronic toxicity studies on OTA in rats (i.e. the ratios between NOAEL from both subacute and subchronic to chronic toxicity studies in rats were 1, see Sections 4.2.2 and 4.2.3) and considered that this is also likely to be the case in pigs.

However, as 3 months represent a much smaller fraction of the total lifespan of pigs as compared to rats, the CONTAM Panel considered it appropriate to apply an UF of 2 for extrapolating the 3-month study in pigs to chronic duration. The CONTAM Panel recognised the uncertainty associated with applying the UF of 2.

For neoplastic effects of OTA, the CONTAM Panel emphasise that a clear distinction between direct and indirect mechanism of genotoxicity was not possible. As a result, the risk characterisation will be either not sufficiently cautious or overcautious depending on which MoAs actually occur.

In the absence of elucidated MoAs for the genotoxicity/carcinogenicity of OTA, the Panel concluded that an MOE of 10,000 needs to be applied to the BMD_{L10} of 14.5 µg/kg bw per day for neoplastic effects (kidney tumours) in the rat. The Panel points out that this MOE is likely to be particularly conservative in this case as the evidence for a direct interaction of OTA with the DNA is inconclusive and other threshold mechanisms may play a role in the formation of kidney tumours. As it was not possible to quantify these variables, the default MOE of 10,000 was applied.

4.7. Occurrence data

4.7.1. Occurrence data used in the present assessment

For the present assessment, it was decided to use data submitted to EFSA between 2009 and 2018 in order to have a data set representing recent/current occurrence levels while retaining a sufficiently high number of samples. The resulting data set included a total of 90,147 analytical results on OTA in food.

Data providers were contacted to clarify inconsistencies identified during the data check. The following modifications were made to the initial data set based on the feedback received:

- 2,008 occurrence values identified as suspect samples were excluded. In the final data set, 53% of the data were taken by selective sampling, 44% by objective sampling while the remaining 3% were either convenient or import sampling, or with no information provided. It was decided to retain the samples with no specific sampling strategy as the % of left-censored samples were in accordance with the ones taken by other sampling strategies.
- The product description of a number of records allowed a more accurate FoodEx classification. In these cases, the samples were reclassified to a more specific, lower level.
- Special attention was given for the 'Product treatment' information. Samples classified as fresh fruit or vegetable with the PRODTREAT field 'dehydration', 'processed', etc. were reclassified accordingly as dried or processed. In the case of figs, samples reported as unprocessed or without any information on the treatment were all assumed to be dried based on the comparison with the levels found in dried figs. As the original occurrence data referred to fresh figs and it cannot be excluded that figs can be contaminated in their fresh form, a factor of 2.86 (taken from EFSA's Raw Primary Commodity Model Database, EFSA, 2019) was applied to adjust the contamination levels for fresh figs taking into account their water content. Without this assumption, the exposure to OTA from consumption of figs would most likely be more overestimated.
- Analytical results with an LOQ above the ML as defined by Commission Regulation (EC) No 1881/2006 were not used for the assessment. In addition, exclusion criteria were also set for those samples where upon carefully checking the occurrence levels and distribution of the

LOQ/LOD values, high percentiles (P95 or P75) of LODs/LOQs were chosen to eliminate extremely high ones reported. The method was applied only for categories considered as an important source of exposure in order to decrease overestimation with the UB exposure scenario (see Table 12). More information about the distribution of LOQ values is provided in Annex, Table 7.

Table 12: LOD/LOQ cut-off values ($\mu\text{g}/\text{kg}$) applied for selected food categories

Food category	Cut-off ($\mu\text{g}/\text{kg}$)	Justification
Ad hoc cut-off values		
'Grains and grain-based products' (covers the ML of 5 $\mu\text{g}/\text{kg}$ for 'Grains for human consumption', 'Grains as crops', 'Unprocessed cereals' and the ML of 3 for 'Bread and rolls', 'Breakfast cereals', 'Fine bakery wares', 'Pasta (Raw)', 'Grain milling products', All products derived from unprocessed cereals, including processed cereal products and cereals intended for direct human consumption)	1.5	P75 of corresponding LOQs
'Fruit nectar'	2	P95 of corresponding LOQs
'Mixed fruit juice'	2	P95 of corresponding LOQs
'Ready-to-eat meal for infants and young children'	2	P95 of corresponding LOQs
'Cereal-based dishes'	2	P75 of corresponding LOQs
'Juice, apple'	2	P95 of corresponding LOQs
'Fruit compote'	2	P75 of corresponding LOQs
ML-based cut-off values		
Dried vine fruits (currants, raisins and sultanas)	10	n.a.
Coffee beans and coffee products (solid)	5	n.a.
Instant coffee, powder	10	n.a.
Wine (including sparkling wine, excluding liqueur wine and wine with an alcoholic strength of not less than 15% vol) and fruit wine	2	n.a.
Aromatised wine, aromatised wine-based drinks and aromatised wine-product cocktails	2	n.a.
Grape juice, concentrated grape juice as reconstituted, grape nectar, grape must and concentrated grape must as reconstituted	2	n.a.
Processed cereal-based food for infants and young children	0.5	n.a.
Pepper, black and white (<i>Piper nigrum</i>), Nutmeg (<i>Myristica fragans</i>), Ginger (<i>Zingiber officinale</i>), Turmeric (<i>Curcuma</i>), <i>Piper</i> spp.	15	n.a.
Chilli pepper (<i>Capsicum frutescens</i>), Cayenne pepper (<i>Capsicum frutescens</i>), Paprika powder (<i>Capsicum</i> spp.) (dried fruits thereof, whole or ground, including chillies, chilli powder, cayenne and paprika)	20	n.a.
Mixtures of spices containing one of the above mentioned	15	n.a.
'Liquorice extract' (flavouring)	80	n.a.
'Liquorice' as root candies and liquorice for herbal infusion	20	n.a.

ML; maximum level; LOQ: limit of quantification; n.a.: not applicable; P75: 75th percentile; P95: 95th percentile;

- Results obtained without information on the analytical method were retained for the assessment if their LOD/LOQ values were sufficiently low comparing to the majority of other samples reported with accepted analytical method.
- Analytical results of samples reported to be measured with PCR-ELISA, Enzyme Immunoassay Tests (EIA), IgG ELISA, electrochemical tests based on potentiometry, AAS, Competitive ELISA) were not considered for the present assessment for reasons of lack of sensitivity, specificity, possible false positive/negatives and/or frequency of use of these methods.

In total 16,256 samples were discarded from the assessment for several reasons including suspect sampling, taken within a total diet survey or subject of a duplicate submission (see Annex, Table 1 for more details).

4.7.1.1. Expression of results

Most of the analytical results were expressed as whole weight. In cases where the results were reported as dry weight, the values were adjusted with the reported moisture content to whole weight. Where information on 'whole weight' or 'dry weight' was not reported (e.g. some samples of coffee beans, spices, paprika powder), these were, upon re-checking, assumed to be whole weights when they were in the range of the other reported occurrence levels within the corresponding category.

4.7.1.2. Occurrence summary statistics

Food samples were submitted by 29 European countries and FEDIOL, the European Vegetable Oil and Protein meal Industry (FEDIOL) (Figure 7) between the years 2009 and 2018 (Figure 8). Mean and P95 levels for OTA in a number of food categories are shown in Table 13. More data on summary statistics of occurrence values are presented in the Annex, Table 2. The proportion of left-censored data (results below the LOD or LOQ) was 75%.

The occurrence data for OTA on 73,891 food samples is available at: <http://doi.org/10.5281/zenodo.3739292>.

Figure 7: Number of food samples in the final data set encoded by European countries: n = 73,891 food samples with results for OTA

Figure 8: Number of food samples in the final data set reported by year for the n = 73,891 food samples with results for OTA

Table 13: Highest 15 mean LB and UB occurrence levels in decreasing order for OTA among food groups with at least six samples (see Annex for additional food items)

FoodEx level2	FoodEx Level3	No of samples	% LC	Mean LB (µg/kg)	Mean UB (µg/kg)
Dietary supplements	Plant extract formula	19	42	35.62	35.79
Fruiting vegetables	Chilli pepper (<i>Capsicum frutescens</i>)	49	27	10.57	10.88
Confectionery (non-chocolate)	Liquorice candies	112	66	9.47	10.30
Spices	Paprika powder	2,670	15	8.92	9.07
Flavourings or essences	Liquorice (<i>Glycyrrhiza glabra</i>)	146	62	6.27	7.13
Spices	Chilli powder	450	24	5.65	5.89
Spices	Allspice (<i>Pimenta dioica</i>)	25	76	5.49	6.08
Spices	Cayenne pepper (<i>Capsicum frutescens</i>)	226	24	4.34	4.72
Bulb vegetables	Garlic, bulb (<i>Allium sativum</i>)	19	74	3.70	5.28
Dried fruits	Dried figs (<i>Ficus carica</i>)	1,936	75	3.63	4.12
Preserved meat	Ham, pork	54	46	3.03	3.09
Spices	Nutmeg (<i>Myristica fragans</i>)	1,069	54	2.95	3.71
Herb and spice mixtures	Curry powder	299	42	2.6	3.1
Herb and spice mixtures	Mixed herbs	56	73	2.5	3.7
Cheese	Cheese (type not specified) ^(a)	15	73	2.2	2.9

LC: left censored; LB: lower bound; UB: upper bound;

(a): Occurrence levels of five samples of Grana Padano cheese are not included here, but considered in the exposure assessment (Annex, Tables 2 and 3).

4.7.1.3. Grouping and selection of food categories for the exposure assessment

In view of the exposure assessment, food data were grouped at different FoodEx levels, and other merged categories used as supplements to FoodEx for the present assessment, taking into consideration several factors including the similarities between food categories, the number of samples and the concentrations observed.

At the most detailed level (FoodEx level 3), the food was retained if more than six samples were available in the category. If less than six samples were available, the levels were compared with similar foods belonging to other categories:

- If the levels were similar, the samples were either grouped together with the similar food, resulting in a new category, or the food was taken into account at a higher (parent) level (FoodEx level 2) if this broader category was well-represented by the available categories at FoodEx level 3.
- If the levels reported were very different, the category was excluded as it was considered insufficiently covered. In order to avoid excluding a specific, but potentially relevant category, a single exception was made for Chocolate and chocolate products for diabetics (n = 4).
- Samples in the categories of the least detailed FoodEx classification (FoodEx level 1) were excluded in cases where no further information was available for a more specific reclassification.

Categories where the analytical results were 100% left censored and OTA contamination was not expected were not taken into account in the assessment. Where in similar food categories on the same level quantified values were found, the samples were grouped together with the similar food according to the same principle as in the first bullet point. For instance in the category 'Black tea, infusion', there were only three left-censored samples, but as in unspecified tea and other tea categories we had quantified values, all tea samples were pooled together (in case of solid teas, after application of a dilution factor) and the mean was calculated based on all of them. For the detailed list of the categories considered, see Annex, Table 2.

Only one honey sample was quantified out of a total 77. Because in the literature no evidence can be found for the presence of OTA in honey, the Panel decided not to consider this category as it would very likely lead to an overestimation of the exposure.

Considering that it is unlikely that fresh cheese gets contaminated with OTA, the contamination levels analysed in cheese (not defined) were not applied on these types.

In case of powdered or concentrated foods (such as coffee, beverage concentrate), dilution factors (see Annex, Table 3) were applied in order to get the ready-to-consume form and match with the consumption data.

Overall, 2,122 samples were excluded from the assessment from the 73,891 samples as they did not fulfil the above selection criteria. In total, 209 categories were created from the 71,769 analytical results for the linking between food occurrence and food consumption data (see Annex, Table 3).

4.7.2. Occurrence of OTA as reported in the public literature

OTA has been detected in foods of plant and animal origin. In foods of plant origin, OTA is frequently found in cereal products, beer, coffee, cacao, chocolate, vegetables, green tea, raisins, grape juice, pistachios, figs, wine, liquorice, chestnuts and spices (e.g. dried red pepper, chilli powder, black pepper, coriander, ginger, cayenne pepper, curcuma and nutmeg).

According to the Rapid Alert System for Food and Feed (RASFF) portal,¹⁴ in the period between January 2016 and June 2019, 25 of in total 87 notifications of OTA were on cereal-based products.

OTA frequently occurs in baby food and breakfast cereals. Rice, barley, oats and wheat are the most contaminated ingredients (Piacentini et al., 2019).

Coffee is frequently infected with ochratoxigenic fungi and temperature affects significantly growth, germination of fungi, as well as the toxin production. Contamination of roasted coffee with OTA is directly related to the processing quality throughout the coffee production chain, from the farming to the roasting processes (Khaneghah et al., 2019).

OTA occurs also frequently in capsicum powder. In the EU, in 2017 and 2018 alone, 41 cases of pepper contamination were reported by the RASFF. Among them, eight notifications were on OTA level exceeding the maximum level (ML). Production of the pepper crop, its transportation, processing and storage are crucial for food safety. OTA has previously been reported in red pepper samples (Santos et al., 2010; Ham et al., 2016), dried chilli pod (Thirumala-Devi et al., 2000; Jalili and Jinap, 2012; Yogendrarajah et al., 2014), chilli powder (Ozbey and Kabak, 2012; Iqbal et al., 2013), red pepper flakes (Tosun and Ozden, 2015), chilli sauce (Iqbal et al., 2011), sweet pepper (Gambacorta et al., 2018) and paprika (Fazekas et al., 2005; Hierro et al., 2008; Ahn et al., 2010). One of the main issues affecting spices is the possible co-occurrence with other mycotoxins such as aflatoxins, zearalenone and deoxynivalenol, due to multiple fungal infection (Santos et al., 2010, 2011).

¹⁴ <https://webgate.ec.europa.eu/rasff-window/portal/?event=SearchForm&cleanSearch=1>

Several studies reported the occurrence of OTA in tea and herbal infusions. It has been shown that toxigenic fungi, mainly *Aspergillus niger* and *Penicillium* spp., grow on tea and herbs leaves, thus inducing OTA accumulation (Haas et al., 2013). OTA was observed in only few samples, but there often at high concentrations, suggesting that under certain conditions, toxin production can be high. The transfer rate during the infusion process of tea was calculated by Malir et al. (2014), who found a mean value of $34.8\% \pm 1.3\%$ for green tea. Transfer rates for green and black teas were reported by Carraturo et al. (2018), with values in the range from 33% to 55%.

A number of studies deal with the occurrence of OTA in botanicals, dietary supplements and traditional herbal remedies on the European market (Ariño et al., 2007; Diana Di Mavungu et al., 2009; Santos et al., 2010; Vaclavic et al., 2013; Veprikova et al., 2015; Gottschalk et al., 2016). Various contaminants may be present in the raw plant material and OTA may be found in dietary supplements obtained from green coffee, liquorice and spices because in commonly used extraction procedures of plant material co-isolation is not avoided.

Contamination of foods of animal origin such as pork meat, pork blood products, poultry kidney or liver with OTA results from consumption of OTA-contaminated feed. Meat products, such as raw ham muscle, cured meats, salami or dry-cured ham can also be directly contaminated during processing or storage. OTA can be produced by *Penicillium nordicum*, which can grow on pork meat during ripening (Rodríguez et al., 2012; Merla et al., 2018).

The Italian Ministry of Health has recommended a guideline value of $1 \mu\text{g}/\text{kg}$ in pork meat products.¹⁵ Therefore, over the last years, a number of studies were performed in Italy on dry cured meat, to better understand the transfer of OTA from feed to pork meat. Several trials have been reported to establish the OTA transfer rate from feed to tissues (Bertuzzi et al., 2013; Altafini et al., 2017). Studies focused on the OTA distribution in tissues, consistently reported the order blood plasma > lung > kidney, heart > bile > liver > fat > muscle, following a dose response. Besides direct contamination because of transfer from the feed the authors identified very high OTA levels in several outer dry-cured ham samples, due to environmental contamination and subsequent mycelia growth on ham surfaces (Dall'Asta et al., 2010; Bertuzzi et al., 2013). OTA occurrence was monitored also in traditional Croatian pork cured meat products (Pleadin et al., 2014) and in French pig liver samples (Hort et al., 2018) with consistent results.

Over the last decade, several studies reported the possible occurrence of OTA in ripened cheese (Dall'Asta et al., 2010; Biancardi et al., 2013; Pattono et al., 2013; Decontardi et al., 2017; Sakin et al., 2018; Anelli et al., 2019; Ramos-Pereira et al., 2019). Considering that the transfer of OTA from feed to ruminants milk is negligible, due to the hydrolytic activity of rumen bacteria, the OTA occurrence in cheese is very likely due to environmental contamination leading to fungal growth on the cheese surface (Kure and Skaar, 2019). Although the common fungi growing on cheese surface have been reported as non-OTA producers (Lund et al., 1995), the growth of uncontrolled moulds during ripening and ageing may occur causing spoilage and possibly mycotoxin production (Ropars et al., 2012; Camardo Leggieri et al., 2020). Very recently, the possible migration of OTA from the crust as far as 1.6 cm in depth was demonstrated in French semi-hard Comté cheese following artificial inoculation with OTA-producing strains (Coton et al., 2019).

Overall, it can be concluded that the occurrence data reported in the public literature are consistent with those available in the EFSA database and used for the exposure assessment in the present opinion.

4.7.3. Effect of processing on OTA occurrence

Many studies have been performed over years to understand the effect of food processing on the concentration of OTA in the final product. Some treatments have been recognised as an effective mitigation strategy, while the efficiency of others is still less known.

In particular, sorting and other cleaning procedures have been demonstrated to be effective in decreasing the OTA content also in food commodities such as nuts, cocoa and coffee beans, through removal of 'hot spots' of contamination. Controlled environmental conditions, mainly humidity and temperature, may avoid fungal growth during storage. High temperatures, which are achieved e.g. during the roasting process, were shown to considerably decrease OTA by thermal degradation.

¹⁵ Ministero della Sanità, 1999. Circolare 09.06.1999. In Sanità MD (ed.). Circolare 09.06.1999 (vol. 135) 11.06.1999. Gazzetta Ufficiale Repubblica Italiana. Available online: <https://www.gazzettaufficiale.it/eli/id/1999/06/26/099A5104/sg>

It is known that cleaning procedures such as gravity separation, dehulling, optical sorting, grading and sieving may represent an effective mitigation step in grain, on account of the distribution of fungal biomass, and the subsequent mycotoxin accumulation, on the kernel external layers (Scudamore and Patel, 2000; Cheli et al., 2013). In general, milling can cause a redistribution of mycotoxins among fractions, with a decrease in toxins in flour and an increase in milling by-products, among them bran (Mousavi Khaneghah et al., 2018; Schaarschmidt and Fauhl-Hassek, 2018). Thermal treatments such as kilning, baking and toasting, are commonly recognised to decrease the overall content of mycotoxins, among them OTA. Besides the effect of the thermal processing, mycotoxins might be affected by other accompanying factors such as additives, ingredients or fermentation (Schaarschmidt and Fauhl-Hassek, 2018).

Although sorting and milling may decrease OTA content in the final fractions, no significant mitigation has been described during the bakery process (Vidal et al., 2014; Schaarschmidt and Fauhl-Hassek, 2018). Extrusion processing, widely used in breakfast cereals manufacture, may reduce mycotoxin levels to varying degrees (e.g. up to 80% in rice). The use of baking soda increases the degradation rate of OTA (Ryu et al., 2019).

Besides cereals, beer can represent another source of OTA exposure (Peters et al., 2017). In brewery, steeping, kilning, malting and fermentation may lead to a significant decrease in OTA. Bertuzzi et al. (2011) reported an average decrease of OTA in the range of 70–90% along the beer production process.

In dried fruits such as figs, removal of damaged fruits also following an automated approach (*i.e.* IR or UV spectroscopy) may reduce final OTA content, especially in combination with proper drying techniques such as controlled ventilation (Mutlu-Ingok and Karbancioglu-Guler, 2014; Benalia et al., 2015; Petrić et al., 2018). Novel technologies such as ozonation and treatment with ionising radiation were shown to reduce OTA in different types of nuts and dried fruit (Pankaj et al., 2018). However, there is a lack of knowledge on the chemistry of the possible degradation products, and on the effect on the overall quality of food material. Therefore, these techniques are not routinely applied in food production.

Herbs and spices are subject to minimal processing before use, hand or optical sorting being the main steps for mycotoxin mitigation. However, in some cases, fumigation and steam treatment are used which may also contribute to the reduction of mycotoxin load. Although seeds, rhizomes and fruits are at risk of field contamination, it has been demonstrated that a principal concern is downstream contamination due to the use of traditional preparation practices particularly the dehydration of fruits through prolonged sun drying of bell and red peppers (Sahar et al., 2017; Weil et al., 2020). Another example is insufficient control of water activity during storage of bulk ground spices, particularly in tropical and subtropical regions which can be mitigated by controlling drying processes and storage conditions.

Fungal growth may affect cocoa beans during the fermentation and drying processes, if not adequately controlled. Cocoa beans surrounded by their pulp are traditionally fermented in heaps. Available data indicate the importance of fermentation length to avoid mycotoxin production, which should not exceed 7 days to minimise OTA contamination (FAO, 2013). At that stage, also lowering the pH and/or the addition of mild organic acid has been shown to reduce to accumulation of OTA to some extent (Copetti et al., 2012). Roasting (generally conducted at 190–210°C for 20–30 min) may significantly reduce the content of OTA via thermal degradation (Manda et al., 2009).

In coffee beans, wet-drying methods are considered more effective in OTA mitigation than the traditional drying method. Proper drying to 11% moisture content is essential to avoid fungal growth during storage and transport.

Several studies have shown that roasting efficiently reduces OTA concentrations (Blanc et al., 1998; Pérez de Obanos et al., 2005; Ferraz et al., 2010; Castellanos-Onorio et al., 2011). Roasting levels (stronger roasting leads to lower OTA levels) and particle size (coarse particles lead to lesser OTA contents than fine ones) seem to be the most relevant factors affecting the final OTA concentration, as reported by Oliveira et al. (2013). Roasting degradation products have been studied and formation of 2'R-OTA and 2-decarboxy-OTA, explain about 40% of the total loss over processing. The remaining degradation is probably due to the binding of OTA to coffee polysaccharides via esterification as a further thermal reaction (Bittner et al., 2013). More recently, OTalpha amide and OTalpha (see Figure 2 of Section 4.1.1 on Toxicokinetics) were identified as minor thermal degradation products of OTA (Bittner et al., 2015). The final occurrence of OTA in the coffee beverage is affected by the preparation method (e.g. brewing, espresso, filtration). Malir et al. (2014) reported that median values for OTA transfer rate from ground roasted coffee to the drinks were the following: 'lungo' (54.9%) > 'americano' (51.1%) > 'espresso' (32.9%) > 'doppio' (29.8%) > 'ristretto' (22.7%). The authors also demonstrated a positive correlation between the OTA transfer rate and the water volume used for the preparation. Slightly acidic conditions were also found positively correlated with a higher OTA extraction.

4.8. Exposure assessment

4.8.1. Current exposure assessment

4.8.1.1. Mean and high dietary exposure

Chronic dietary exposure was estimated across Europe following the methodology described in Section 3.5. A total of 38 dietary surveys, carried out in 22 different Member States, were selected for this assessment. These dietary surveys and the number of subjects available per age class are described in the Annex, Table 4).

Table 14 summarises the chronic dietary exposure estimates for OTA across the 38 dietary surveys. Detailed summary statistics on the exposure estimates calculated for each dietary survey are presented in the Annex, Table 5.

Table 14: Mean and 95th percentile of chronic exposure estimates at the LB and UB for OTA

Age class ^(a)	Number of surveys	Mean dietary exposure (ng/kg bw per day)					
		Minimum		Median		Maximum	
		LB	UB	LB	UB	LB	UB
Infants	11	0.64	2.53	1.93	5.66	8.64	15.71
Toddlers	14	3.32	7.34	5.72	12.33	9.13	17.79
Other children	19	2.91	7.40	5.03	10.78	8.05	14.36
Adolescents	18	2.20	5.15	3.26	6.02	4.54	8.09
Adults	19	1.66	3.47	2.41	5.09	3.84	6.03
Elderly	18	1.30	3.09	2.07	4.54	3.57	6.18
Very elderly	14	1.10	2.62	2.08	4.52	3.59	5.32
Pregnant women	2	1.49	3.28	1.88	3.81	2.26	4.33
Lactating women	2	1.66	4.07	2.11	4.48	2.57	4.88
Age class ^(a)	Number of surveys	95th percentile dietary exposure (ng/kg bw per day) ^(b)					
		Minimum		Median		Maximum	
		LB	UB	LB	UB	LB	UB
Infants	10	2.58	7.34	6.86	14.22	30.36	51.69
Toddlers	12	9.97	16.59	12.20	22.01	22.23	37.13
Other children	19	6.26	14.40	10.09	19.44	17.92	28.06
Adolescents	17	4.82	9.93	6.55	11.38	10.46	15.70
Adults	19	3.86	7.56	5.44	10.36	8.88	12.65
Elderly	18	3.16	6.68	4.30	8.61	8.60	13.71
Very elderly	10	2.40	5.13	3.97	8.45	5.22	9.19
Pregnant women	2	3.07	6.21	4.06	7.23	5.04	8.26
Lactating women	2	3.11	6.40	4.51	8.23	5.92	10.06

bw: body weight; LB: lower bound; UB: upper bound.

(a): Section 2.3 describes the age range within each age class.

(b): The 95th percentile estimates obtained on dietary surveys/age classes with less than 60 observations may not be statistically robust (EFSA, 2011a). Those estimates were not included in this table.

As can be seen in Table 14, the mean exposure estimates ranged from 0.64 (minimum LB)/2.53 (minimum UB) to 9.13 (maximum LB)/17.79 (maximum UB) ng/kg bw per day across dietary surveys and age groups. At the 95th percentile, exposure estimates ranged from 2.40 (minimum LB)/5.13 (minimum UB) to 30.36 (maximum LB)/51.69 ng/kg (maximum UB) bw per day.

Dietary exposure in specific groups of the population, namely pregnant and lactating women (each represented with two survey), was within the range of exposure estimates for the adult population.

4.8.1.2. Contribution of different food groups to the total dietary exposure

Figures 9, 10 and 11 summarise the proportions of contributors of exposure (LB) in 11 broad food groups together with the magnitude of exposure for each the surveys in age groups 'Toddlers', 'Other Children', 'Adolescents', 'Adults', 'Elderly' and 'Very elderly'. As shown in the figures, preserved meat, cheese, grains and grain-based products are main contributors across all surveys. However, contribution of the first two varies to a larger extent, while contribution of grain-based products remains more constant. Dried fruits, and fresh fruits such as grapes, figs and dates (see occurrence values and categories considered in the Annex, Table 3) as well as fruit juices and nectars were also contributing to the exposure in some of the 'Toddlers' and 'Other children' surveys, albeit, to a lesser extent than the three major contributor groups. Non-chocolate confectionary is a significant source of exposure in countries where liquorice-based sweets are frequently consumed (in particular Finland, the Netherlands, Sweden and Denmark). All subcategories as designated and depicted in Figures 9, 10 and 11 are listed in the Annex, Tables 3 and 8 where information about the percentages is provided. Occurrence levels of selected subcategories of the main contributing foods are shown in Table 15, except those from 'Grain and grain-based products' where there are 55 subcategories and thus, they could not be included in the table.

Table 15: Occurrence levels and subcategories of the main contributing foods considered in the exposure assessment and shown in Figures 9, 10 and 11

Category as listed in Figures 9, 10 and 11	Linking category ^(c)	LB MEAN µg/kg	UB MEAN µg/kg
Cheese	Cheese (on Foodex2 level) ^(a)	1.68	2.43
Meat and meat products	Boar meat (<i>Sus scrofa</i>)	0.05	0.13
	Ham, pork	3.03	3.09
	Liver and kidney, farmed animals	0.04	4.67
	Pastes, pâtés and terrines	0.07	0.12
	Preserved meat	2.20	2.27
	Sausages	0.94	1.11
	Fresh and dried fruits, and fruit products	Dried apricots (<i>Prunus armeniaca</i>)	0.28
Dried dates (<i>Phoenix dactylifera</i>)		1.83	2.27
Dried figs (<i>Ficus carica</i>)		3.63	4.12
Dried fruits (not defined)		2.16	2.74
Dried vine fruits (currants, raisins and sultanas)		1.86	2.44
Berries and small fruits (not defined)		0.13	1.61
Dates (<i>Phoenix dactylifera</i>)		0.01	1.72
Figs ^(b)		1.27	1.44
Fruit, canned		0.02	0.25
Jam, marmalade and other fruit spreads		0.13	0.65
Grains and grain-based products ^(d)		Bread and rolls	0.16
	Breakfast cereals	0.15	0.42
	Fine bakery wares	0.05	0.26
	Muesli	0.23	0.43
	Pasta (Raw)	0.07	0.36
	Pastries and cakes	0.15	0.48

(a): Fresh cheeses, such as mozzarella, robiola, etc. were not taken into consideration.

(b): Derived from occurrence levels of 'Dried figs'.

(c): Category used in the exposure assessment for matching the occurrence and consumption data.

(d): Includes 'Grains for human consumption', 'Grain milling products', 'Bread and rolls', 'Pasta (Raw)', 'Breakfast cereals', 'Fine bakery wares' in 55 subcategories (Annex, Table 3).

In the case of infants, cheese and meat products are the most important contributors to OTA exposures together with various grains and grain-based products (such as bread and rolls, various cereal flakes, rice, popped cereals). Food groups contributing more than 5% to the LB exposure estimates in at least one dietary survey are summarised in the Annex, Table 6.

The Panel acknowledged that data from the younger age groups (i.e. 'Toddlers', 'Children' and 'Adolescents') showed some levels of intake from consumption of alcoholic beverages. These exposure estimates (which are very low) are most likely a result of the indirect consumption of alcoholic beverages as ingredients of composite foods.

As already noted above, Figures 9, 10 and 11 below summarise the contribution of different food categories to OTA exposures in different surveys. Notably the categories used in these figures do not correspond to FoodEx categories.

Figure 9: Contributors of exposure of OTA among different countries/surveys in 'Toddlers' and 'Other Children'

Figure 10: Contributors of exposure of OTA among different countries/surveys in 'Adolescents' and 'Adults'

Figure 11: Contributors of exposure of OTA among different countries/surveys in 'Elderly' and 'Very Elderly'

4.8.1.3. Comparison of occurrence levels and exposure with the previous EFSA opinion on OTA

In 2006, data from a SCOOP (Socioeconomic sciences: communicating outcomes oriented to policy) report from 2002 (European Community, 2002) were used as a basis for the assessment of the exposure. It included seven food categories representing the supposed main contributors to OTA exposure. These categories were cereals and cereal products, wine, beer, grape juice, brewed coffee, cocoa and cocoa products as well as pork meat (see Table 16).

Table 16: Comparison of occurrence levels used in the 2006 EFSA opinion with levels detected in the current database in the corresponding food categories

2006 occurrence data – taken from European Community (2002)			2019 occurrence data – taken from EFSA data warehouse		
Food category	N	Mean ($\mu\text{g}/\text{kg}$) ^(a)	Food category	N	LB/UB Mean ($\mu\text{g}/\text{kg}$)
Cereals and cereal products	5,180	0.29	Breakfast cereals	1,882	0.18/0.44
			Grain milling products	4,409	0.29/0.55
			Grains for human consumption	6,852	0.22/0.50
Beer	496	0.03	Beer and beer-like beverages	1,755	0.04/0.26
Wine	1,470	0.36	Wine	5,692	0.06/0.25
Grape juice	146	0.55	Grape juice	1,809	0.18/0.27
Cocoa and cocoa products	547	0.24	Cocoa and cocoa products	1,204	0.57/0.83
Pork meat/edible offal	1,860	0.20	Ham, pork	54	3.03/3.09
			Pork meat	112	0.0/0.2 (100% left censored)
			Pork kidney	2,327	0.04/5.1
Roasted ground coffee (dry weight)	1,184	0.72	Roasted ground coffee (whole weight)	1,651	0.56/0.94

LB: lower bound; N: number of samples; UB: upper bound;

(a): Mean was calculated according to the following criteria: 1) If LOD and LOQ were available, mean level was calculated using LOD/2 for results lower than the LOD. For results between LOD and LOQ, numerical values, if available, were used. 2) If only LOQ was available, or if numerical values between LOD and LOQ were not available, LOQ/2 for values below the LOQ were used (European Community, 2002).

As can be seen in Table 16, the occurrence levels in the database used for the present assessment are similar to those in the seven main food categories used in the EFSA assessment of 2006. However, the current exposure estimate considered 210 subcategories in a wide range of food products including also data on other grain-based products, cheese, various meat products, tree nuts, liquorice-containing products and dried fruits that were previously not considered. This resulted in slightly higher exposure estimates. Moreover, because in 2006, the EFSA Comprehensive Food Consumption Database was not yet available the Concise Database was used, allowing only less refined estimates. Thus, in 2006, mean exposure of an average adult consumer varied between 2 and 3 ng/kg bw per day while in the current assessment, mean LB/UB exposures range between 1.68/3.51 and 3.84/6.05 ng/kg bw per day in 'Adults'. In addition, in 2006, the use of the Concise Database did not allow an accurate assessment of the dietary exposures of age classes other than 'Adults'.

4.9. Exposure assessment of infants fed on human milk

4.9.1. Occurrence of OTA in human milk in Europe

The occurrence of OTA in human milk in European populations was investigated intensely over the last two decades. In terms of analytical performance, methods are significantly improved over the last three decades in particular in terms of sensitivity and selectivity. Therefore, the CONTAM Panel decided to list in Table 17 only those papers reporting sufficient information on the analytical performance and the data collected.

Table 17 presents an overview of recent studies on occurrence of OTA in human milk potentially useful for derivation of occurrence levels for OTA in breast milk. In all these studies consistently lower OTA values (all in the same order of magnitude) are reported compared to the older studies. In Table 17 study design, concentration median/mean/range, LOQ and LODs are indicated.

Table 17: Studies on OTA levels in breast milk in Europe

Study population	Analytical method	No of samples (No of positive samples)	Median of positive samples (ng/L)	Mean \pm SD positive samples (ng/L)	Mean \pm SD all samples (ng/L)	Concentration range of positive samples (ng/L)	LOD (ng/L)	LOQ (ng/L)	Reference
Lactating women from mid north Sweden. Milk sampled 6 weeks after delivery (mature milk) and 2–3 h after the previous feed. No selection/exclusion criteria reported	LC-FD	40 (23)	n.r.	n.r.	n.r.	10.0–40.0	10	40	Breitholtz-Emanuelsson et al. (1993)
Milk samples from Swiss mothers living north of the Alps. No further selection criteria reported	LC-FD	40 (4)	n.r.	n.r.	n.r.	5–14	n.r.	5–10	Zimmerli and Dick (1995)
Samples obtained May–August in different regions of Norway. Elverum (south east); Trondheim (middle coast); Bodo (north). No selection/exclusion criteria reported	LC-FD	Total: 115 (38) Elverum: 48 (20) Trondheim: 19 (11) Bodo: 48 (7)	Total: 30	Total: n.r. Elverum: 43.2 Trondheim: 49.0 Bodo: 27.4	n.r.	10–130	n.r.	10	Skaug et al. (1998)
Samples from healthy women (19–35 years old) from one (not the first) morning feed. Mothers were asked for but not selected because of their dietary habits	LC-FD	80 (17)	16	30	n.r.	10–182	n.r.	10	Skaug et al. (2001)
Samples of mature milk from Polish mothers. No information on selection criteria	ELISA	78 (40)	n.r.	6.8 \pm 4.9	n.r.	2.4–16.0	n.r.	5	Karwowska et al. (2004)

Study population	Analytical method	No of samples (No of positive samples)	Median of positive samples (ng/L)	Mean \pm SD positive samples (ng/L)	Mean \pm SD all samples (ng/L)	Concentration range of positive samples (ng/L)	LOD (ng/L)	LOQ (ng/L)	Reference
Italian mothers from different parts of Lombardy. Milk sampled 3–4 days after birth. No preselection of mothers based on dietary habits	LC-FD	231 (198)	4	6.01 \pm 8.31	n.r.	0.5–17	0.5	n.r.	Turconi et al. (2004)
Milk from Polish mothers obtained 3–4 days after labour	LC-FD	13 (5)	n.r.	5.6 \pm 4	n.r.	5.3–17	5	15	Postupolski et al. (2006)
Milk obtained from Slovak mothers from 0 to 6 months after delivery	LC-FD	76 (23)	n.r.	n.r.	n.r.	4.8–60.3	4.8	14.4	Dostal et al. (2008)
Mature milk samples collected from Italian mothers 30 days after delivery. Only healthy non-smoking, non-drinking mothers with healthy babies were enrolled in the study	LC-FD	82 (61)	n.r.	30.43 \pm 8.8	n.r.	5–405	2	5	Galvano et al. (2008)
Samples from 57 Italian and non-Italian mothers obtained 3–4 days after delivery in a hospital in Northern Italy	LC-FD	57 (41)	n.r.	10.0 \pm 15.6	n.r.	1.0–75.1	0.5	1.0	Biasucci et al. (2011)
Milk collected from 90 German mothers, 30 in Nordrhein Westfalen (NRW) and 60 in Niedersachsen (NS)	LC-MS	90 in total NRW 30 (7) NS 60 (6)	n.r.	n.r.	24.41 \pm 21.1 (NRW) 14.4 \pm 15.1 (NS)	n.r.	10	30	Muñoz et al. (2013)

Study population	Analytical method	No of samples (No of positive samples)	Median of positive samples (ng/L)	Mean \pm SD positive samples (ng/L)	Mean \pm SD all samples (ng/L)	Concentration range of positive samples (ng/L)	LOD (ng/L)	LOQ (ng/L)	Reference
Healthy (30) and coeliac (35, on a gluten-free diet) breast feeding mothers. Samples collected three times daily for three consecutive days between 2 weeks and 4 months after birth. No further selection/exclusion criteria reported	LC-FD	453 (7)	n.r.	n.r.	n.r.	17–123	n.r.	34	Valitutti et al. (2018)

ELISA: enzyme-linked immunosorbent assay; LC-FD: liquid chromatography-fluorescence detection; LC-MS: liquid chromatography-mass spectroscopy; LOD: limit of quantification; LOQ: limit of quantification; n.r.: not reported; SD: standard deviation.

Overall, it can be seen that occurrence values are affected by a large variability within studies, probably owed to study design and specificity and sensitivity of methods. For most of the studies, individual data were not provided. In several studies only concentration ranges but no mean values have been reported (Breitholtz-Emanuelsson et al., 1993; Zimmerli and Dick, 1995; Dostal et al., 2008; Valitutti et al., 2018). The studies from Skaug et al. (1998, 2001) showed a high variability, probably due to the lower specificity of the analytical methods compared to those currently used. The study from Postupolski et al. (2006) had a rather small study population while the values derived by Galvano et al. (2008) had a rather high variability.

After evaluation of the data as reported, the CONTAM Panel decided to base the exposure assessment on the most recent studies, i.e. Muñoz et al. (2013), Biasucci et al. (2011) and Valitutti et al. (2018). In order to provide a transparent exposure assessment, the study authors were contacted and the raw data kindly provided by Gisela Degen (Muñoz et al., 2013), Filippo Rossi (Biasucci et al., 2011) and Carlo Brera and Barbara de Santis (Valitutti et al., 2018) and are presented in Appendix G.

Breast milk has a different nutritional composition in different stages and is designated as colostrum (1–5 days post-partum), transitional milk (6–14 days post-partum) and mature milk (15 days to 15 months post-partum). In particular colostrum has a higher protein content as compared to transitional or mature milk (EFSA NDA Panel, 2013). Muñoz et al. (2014) found in a comparative study that milk-to-plasma ratio, measured over a period of 4 months, is significantly higher ($p = 0.001$) during the first week of lactation (0.40 ± 0.26) compared to the following period (i.e. 0.26 ± 0.19 at 4 months), probably in consideration of the high OTA affinity with proteins. In the same study, the authors also found that individual OTA levels in mature milk varied considerably individually during the study period but overall mean concentration levels did not vary substantially over a period of 6 months (mature milk was measured at 15–30 days, 2, 4 and 6 months). Notably several subjects dropped out early during the study and only in four mothers was it possible to receive milk samples until the very end of the study. Considering the particular composition of colostrum in comparison to mature milk and the possibly different excretion rate of OTA to colostrum and the short duration of feeding of colostrum, the CONTAM Panel concluded that such samples are likely not representative of exposure *via* breast feeding during the first 6 months of the life period of an infant. Therefore, the data from Biasucci et al. (2011), which were exclusively colostrum samples (see Appendix G, Table G.2), were not considered in the analysis.

In the study from Valitutti et al. (2018), mature milk from groups of healthy and coeliac mothers was collected three times daily over a period of 3 days (see Appendix G, Tables G.3 and G.4). However, out of a total of 453 milk samples, OTA was detected only in seven samples and these came mainly from the same individual. It was concluded that these results could not be used for a representative exposure assessment because this would be driven mainly by non-detects and by high OTA levels detected in a single individual.

The CONTAM Panel concluded that the study from Muñoz et al. (2013), obtained using a confirmatory LC-MS method, presenting a good sensitivity and enrolling a sufficient amount of individuals/breast milk samples is the most appropriate investigation for deriving a reliable and representative mean OTA occurrence level for the exposure assessment from human milk. In this study (see also Table 17), a total of 90 breast milk samples from two different cities in Germany (Dortmund and Hannover) were analysed (for individual data, see Appendix G Table G.1). For reasons already described above the data on colostrum were omitted from use in the exposure assessment and only data obtained for transitory and mature milk were used for deriving OTA exposure for breastfed infants for the period from birth to 6 months of age. For the remaining 71 milk samples, median and P95 LB levels were 13 and 43 ng/mL, respectively.

The CONTAM Panel concluded that the median and the 95th percentile of the concentrations are the most appropriate parameters to be used for the exposure assessment. These provide information on the median exposure of infants and also on the infants consuming milk with high OTA concentrations. The approach is further supported by the consideration that infants are a sensitive population, and they are consuming only breast milk from one mother with a daily exposure to a toxin that has the potential to accumulate in the body.

4.9.2. Breast milk consumption and exposure assessment of infants fed on human milk

Thus, for the exposure assessment of infants below 6 months of age to OTA via breast milk, a value of 3 months was selected, assuming an average body weight of 6.1 kg, with an estimated

average daily consumption of 800 mL per day and a high consumption of 1,200 mL per day of human milk (EFSA NDA Panel, 2013) was combined with the median and P95 occurrence levels mentioned above. Based on the reported median concentration of OTA of 13 ng/L and a 95th percentile (P95) concentration of OTA of 43 ng/L in human milk (transitional and mature milk combined) the dietary exposure to OTA ranged from 1.7 to 5.6 ng/kg bw per day for infants with an average milk consumption and from 2.6 to 8.5 ng/kg bw per day for infants with a high milk consumption.

These intakes are actually in the lower part of those based on consumption of other food (Table 14), being for the mean LB exposure 0.65 to 8.64 ng/kg bw per day (lowest LB-highest LB) and for high exposure (P95) 2.57 to 30.36 ng/kg bw per day (lowest LB-highest LB). It should be noted that in these calculations on exposure from food, the class of infants actually covers the period up to 12 months. Breastfeeding may also cover a period of 12 months, but after a number of months, the infants will receive additional food.

4.10. Risk characterisation

4.10.1. Non-neoplastic effects

The CONTAM Panel selected the BMDL₁₀ of 4.73 µg OTA/kg bw per day for increased incidence of microscopic kidney lesions seen in a 3-month study with female pigs (Krogh et al., 1974) as a reference point for the risk characterisation of non-neoplastic effects. Comparison of the chronic dietary exposure to OTA across dietary surveys and age groups as reported in Table 14 of Section 4.7 Exposure assessment to this BMDL₁₀ results in MOE values that range from 7391 (lowest minimum LB exposure across national consumption surveys) to 266 (highest maximum UB exposure across national consumption surveys) for the mean exposure estimates, and from 1971 (lowest minimum LB) to 92 (highest maximum UB exposure) for the 95th percentile exposure estimates across dietary surveys and age groups (see Table 18 below).

Table 18: Margins of exposure (MOE) values of the different age groups to the BMDL₁₀ of 4.73 µg OTA/kg bw per day for increased incidence of microscopic kidney lesions upon OTA exposure of pigs

Age group	MOE calculated from mean dietary exposure						MOE calculated from P95 dietary exposure					
	Minimum		Median		Maximum		Minimum		Median		Maximum	
	LB	UB	LB	UB	LB	UB	LB	UB	LB	UB	LB	UB
Infants	7,391	1,870	2,451	836	547	301	1,833	644	690	333	156	92
Toddlers	1,425	644	827	384	518	266	474	285	388	215	213	127
Other children	1,625	639	940	439	588	329	756	328	469	243	264	169
Adolescents	2,150	918	1,451	786	1,042	585	981	476	722	416	452	301
Adults	2,849	1,363	1,963	929	1,232	784	1,225	626	869	457	533	374
Elderly	3,638	1,531	2,285	1,042	1,325	765	1,497	708	1,100	549	550	345
Very elderly	4,300	1,805	2,274	1,046	1,318	889	1,971	922	1,191	560	906	515
Pregnant women	3,174	1,442	2,516	1,241	2,093	1,092	1,541	762	1,165	654	938	573
Lactating women	2,849	1,162	2,242	1,056	1,840	969	1,521	739	1,049	575	799	470

LB: lower bound; UB: upper bound; P95: 95th percentile.

Comparison of dietary exposure of infants from breastfeeding, with this BMDL₁₀ results in MOE values of 2783 and 1819 at median OTA concentrations in milk and of 845 and 556 at 95th percentile OTA concentrations in milk in average and high breast milk consumers, respectively.

The CONTAM Panel considered that based on the available toxicity data and taking inter- and intraspecies variations and the relatively short duration of the pig study (3 months) used for deriving a non-neoplastic chronic BMDL₁₀, an MOE of 200 would be sufficient to conclude on a low health concern for non-neoplastic effects of OTA. As can be seen in Table 19, comparison of exposures with the BMDL₁₀ based on the non-neoplastic endpoint resulted in MOEs of more than 200 in most

consumer groups. Exceptions are 95th percentile exposures at maximum LB in the age group of 'Infants' and at maximum UB in the age group of 'Infants', 'Toddlers' and 'Other children' indicating a possible health concern for these age groups.

MOEs in breastfed infants were all above 200 indicating a low health concern.

The CONTAM Panel concluded that these MOEs indicate a possible health concern for non-neoplastic effects of OTA for high consumers in the young age groups.

4.10.2. Neoplastic effects

The CONTAM Panel selected the BMDL₁₀ of 14.5 µg OTA/kg bw per day for increased combined incidences of adenomas and carcinomas in male rats in a chronic study (NTP, 1989) as a reference point for the risk characterisation of neoplastic effects. Comparison of the chronic dietary exposure to OTA across dietary surveys and age groups reported in Table 14 of Section 4.7 Exposure assessment to this BMDL₁₀ results in MOE values (see Table 20 below) that range from 22,656 (lowest minimum LB exposure) to 815 (highest maximum UB exposure) for the mean exposure estimates, and from 6,042 (lowest minimum LB exposure) to 281 (highest maximum UB exposure) for the 95th percentile exposure estimates across dietary surveys and age groups.

Table 19: Margins of exposure (MOE) values of the different age groups to the BMDL₁₀ of 14.5 µg OTA/kg bw per day calculated from increased combined incidences of kidney tumours in male rats

Age group	MOE calculated from mean dietary exposure						MOE calculated from P95 dietary exposure					
	Minimum		Median		Maximum		Minimum		Median		Maximum	
	LB	UB	LB	UB	LB	UB	LB	UB	LB	UB	LB	UB
Infants	22,656	5,731	7,513	2,562	1,678	923	5,620	1,975	2,114	1,020	478	281
Toddlers	4,367	1,975	2,535	1,176	1,588	815	1,454	874	1,189	659	652	391
Other children	4,983	1,959	2,883	1,345	1,801	1,010	2,316	1,007	1,437	746	809	517
Adolescents	6,591	2,816	4,448	2,409	3,194	1,792	3,008	1,460	2,214	1,274	1,386	924
Adults	8,735	4,179	6,017	2,849	3,776	2,405	3,756	1,918	2,665	1,400	1,633	1,146
Elderly	11,154	4,693	7,005	3,194	4,062	2,346	4,589	2,171	3,372	1,684	1,686	1,058
Very elderly	13,182	5,534	6,971	3,208	4,039	2,726	6,042	2,827	3,652	1,716	2,778	1,578
Pregnant women	9,732	4,421	7,713	3,806	6,416	3,349	4,723	2,335	3,571	2,006	2,877	1,755
Lactating women	8,735	3,563	6,872	3,237	5,642	2,971	4,662	2,266	3,215	1,762	2,449	1,441

LB: lower bound; UB: upper bound; P95: 95th percentile.

Comparison of dietary exposure of infants from breastfeeding, with this BMDL₁₀ results in MOE values of 8,529 and 5,577 at median OTA concentrations in milk and 2,589 and 1,706 at 95th percentile OTA concentrations in milk in average and high breast milk consumers, respectively.

For substances that are both genotoxic and carcinogenic, EFSA (2005) and EFSA Scientific Committee (2012a) stated that an MOE of 10,000 or higher if based on a BMDL₁₀ from an animal carcinogenicity study would be of low health concern.

However, as can be seen in Table 20, the calculated MOEs are below 10,000 in most of the dietary surveys, in particular for 95th percentile exposures which are all far below 10,000. In breastfed infants, the MOEs are below 10,000 in all scenarios. The CONTAM Panel noted that these MOEs would indicate a possible health concern but the CONTAM Panel also notes the uncertainties associated with the interpretation of the mode of action for carcinogenicity (see below Section 4.11 on Uncertainties).

For neoplastic effects of OTA, the CONTAM Panel emphasises, that it was not possible to make a clear distinction between a direct and an indirect mechanism of genotoxicity. As a result, the risk characterisation will be either not sufficiently cautious or overcautious depending on which MoAs actually take place. The Panel points out that the MOE of 10,000 is likely to be most conservative in this case as the evidence for a direct interaction of OTA with the DNA is inconclusive and alternative thresholded mechanisms may play a role in the formation of kidney tumours.

Pending the elucidation of the MoAs for the genotoxicity/carcinogenicity of OTA, the Panel concluded that an MOE of 10,000 to the neoplastic reference point is warranted for the risk characterisation of OTA, albeit being the most conservative approach until the MoAs are clarified.

4.11. Uncertainty analysis

The evaluation of the inherent uncertainties in the present assessment was performed following the guidance of the Scientific Committee related to uncertainties in dietary exposure assessment (EFSA, 2007). The CONTAM Panel took note of the new guidance on uncertainties of the Scientific Committee (EFSA Scientific Committee, 2018), but it was not implemented in this opinion.

4.11.1. Assessment objectives

The objectives of the assessment are clearly laid down in the terms of reference.

4.11.2. Occurrence data/consumption data/exposure assessment

4.11.2.1. Occurrence data

The number of occurrence data submitted varied considerably between the different food categories. Most samples belonged to category 'Grains' and 'Grain-based products'. The lower the number of measured samples, the higher the uncertainty related to the levels of OTA in food commodities which was an issue for example for cheese and certain preserved meat products where relatively few data were available.

It was noted that the uncertainties regarding the UB mean occurrence levels can be higher for non-homogenous food samples where contamination levels below the LOQ/LOD are less likely to occur.

About 55% of the occurrence data used for the exposure assessment were collected from two EU countries (Germany and The Netherlands) and thus the assessment might not fully represent the contamination of food in other countries or the EU as a whole.

To reduce the uncertainty in the levels and inherent exposure assessment, LOQ/LOD cut-off values were applied based on the existing MLs in Commission Regulation (EC) No 1881/2006 and also to certain important contributing food categories where particularly high LOQs/LODs were found and where the differences between the mean UB/LB values were large. In the final database used for the assessment, 75% of the samples were left-censored. An ad hoc scenario was carried out without the application of LOQ cut-off values in order to check the impact of their application (see Annex, Table 5). The results show slightly higher UB exposures i.e. slightly greater differences between LB and UB estimates. Comparing the ranges, mean and 95th percentile levels in the current assessment are ranging from 0.64 to 17.79 and from 2.4 to 51.7 ng/kg bw per day, while in the ad hoc scenario, the same parameters were 0.61 to 17.36 and 2.23 to 50.53 ng/kg bw per day.

Likewise, the lack of information on the analytical method used to analyse some food samples (relevant for about 16% of the data) adds uncertainty regarding reported vs. actual concentrations of OTA.

Re-classifications have been carried out regarding the 'product treatment' field of the occurrence data records (e.g. where processed/dehydrated fruits were classified as fresh have been reclassified to the corresponding category). However, not all the data providers indicated the product treatment information, thus in some cases the reclassification was made based on assumption (e.g. in the case of figs). This may result in over- or underestimation of the exposure.

In the final occurrence database 678 analytical results were found to be above the MLs of Commission Regulation (EC) No 1881/2006. To evaluate their impact on the overall assessment, an ad hoc scenario with the exclusion of non-compliant samples was carried out which showed only a very minor impact on the exposure results.

4.11.2.2. Consumption data

Uncertainties and limitations related to the use of the EFSA Comprehensive Food Consumption Database were described by EFSA (EFSA, 2011a) and are therefore not further detailed in this opinion. Generally, these limitations and uncertainties relate to the use of different dietary survey methodologies, standard portion sizes, representativeness of samples included in surveys or to the inclusion of consumption surveys covering only few days to estimate high percentiles of chronic exposure.

4.11.2.3. Dietary exposure assessment

Further sources of uncertainty are related to the different assumptions done for the present assessment, mainly for the linkage between the occurrence and consumption data. In particular:

- A number of foodstuffs were grouped at the second level of the FoodEx, assuming homogeneity of the contamination levels, which could lead to both over- and underestimation of the exposure.
- According to the literature (see Section 4.7.2 Occurrence of OTA as reported in public literature), certain types of cheese, particularly ripened ones might have higher OTA contamination levels and predominantly in the crust as they get contaminated with OTA during manufacturing or storing. Consequently, cheeses with edible rind as well as the grated ones where the outer part is also included in the final product are assumed to be the main contributors of exposure originated from cheese. However, most of the occurrence data were available on unspecified cheese, and also in the majority of the food consumption records in the Comprehensive Database the type of cheese was not reported either. Thus, the only possible refinement was to exclude the fresh types of cheeses from the assessment, where it was reported in the consumption surveys. As the impact of this refinement was minor, especially on those surveys where only unspecified cheese was reported, OTA exposure from cheese consumption is most likely overestimated.
- In case of food supplements, based on the text description of the samples, highest contamination levels were found in the ones containing liquorice and green coffee extractions. However, this level of specification was not possible to be distinguished from the consumption side, which most likely results in overestimation of the exposure as the levels were applied to all 'Plant based formula' consumed.

4.11.2.4. Exposure assessment for breast fed infants

The exposure assessment was based on relatively few measured occurrence data from a single study in Germany with a limited number of samples (Muñoz et al., 2013) together with default values for consumption. These occurrence data are probably not representative of the situation in the entire EU.

4.11.3. Hazard characterisation

For the microscopic kidney lesions used for calculation of a non-neoplastic BMD only incidence but no severity data were available. The EFSA guidance on default values (EFSA Scientific Committee, 2012a) proposes the use of an UF of 2 from subchronic to chronic duration in rodents. The use of an UF of 2 for extrapolating from a 3-month study in pigs to a chronic effect is an assumption associated with uncertainty as 3 months represent a relatively shorter fraction of the natural lifespan of a pig as compared to the lifespan of rats a larger UF could be applied. Indirect mechanism of genotoxicity and non- genotoxic MoAs are likely to play major roles in the carcinogenic activity of OTA, albeit to which extent cannot be quantified. The application of an MOE of 10,000, following EFSA guidance is particularly conservative in this case, because such an MOE applies for compounds that are directly genotoxic and carcinogenic and the evidence for a direct interaction of OTA with the DNA is inconclusive. The interpretation of the relevance of the findings of the raised protein concentrations in urine in infants exposed to high levels of OTA *via* their mothers is hampered by the small sample size in this study.

4.11.4. Summary of uncertainties

In Table 20, a summary of the uncertainty evaluation is presented, highlighting the main sources of uncertainty and indicating an estimate of whether the source of uncertainty leads to over/underestimation of the resulting risk.

Table 20: Summary of major uncertainties in the risk assessment of OTA in food

Sources of uncertainty	Direction ^(a)
Assumption that OTA-induced mutations result from direct genotoxicity	+
Assumption that OTA-induced mutations result from indirect genotoxicity	-
Use of kidney lesion incidences for non-neoplastic effect characterisation	+
Use of an uncertainty factor of 2 for extrapolation from a 3-month study in pigs to chronic effects	-
Small sample size in human study where raised protein concentrations were seen	+/-
Extrapolation of the occurrence data submitted mainly by two countries to the whole of Europe	+/-
Methodology used to estimate 95th percentile chronic exposure based on consumption surveys only covering a few days	+
Consideration of all cheese with equal contamination level	+
Extrapolation of occurrence data from one study used for exposure assessment for breastfed infants to the whole of Europe	+/-

(a): + = uncertainty with potential to cause overestimation of exposure/risk; - = uncertainty with potential to cause underestimation of exposure/risk. Extent of potential over/underestimation might differ in direction.

The overall uncertainty incurred with the present assessment is high. The assessment is more likely to overestimate than to underestimate the risk.

5. Conclusions

5.1. General conclusions

OTA is produced by various fungi of the genus *Aspergillus* and *Penicillium*, e.g. *A. ochraceus*, *A. carbonarius* and *P. verrucosum*. OTA is stable to moderate heating but losses ranging up to 90% are observed at temperatures above 180°C. OTA in food is analysed by LC-MS, LC-MS/MS and HPLC methods.

5.2. Toxicokinetics

- OTA is rapidly absorbed and distributed following ingestion.
- OTA is slowly eliminated from blood, with plasma half-lives ranging from several days in rodents and pigs to several weeks in non-human primates and humans. Due to the slow elimination and excretion, and low rate of metabolism, OTA has the potential to bioaccumulate in the organism.
- The major metabolic pathway of OTA is hydrolysis to OTalpha, followed by conjugation with glucuronic acid.

5.3. Transfer to food

- Because of its long half-life OTA may accumulate in animal tissues and thus is found in meat and meat products in particular of non-ruminants such as pigs. In fish, half-life of OTA is shorter and OTA does not accumulate in edible parts, i.e. muscle tissue.
- Based on efficient degradation in the rumen, OTA levels in cow milk are low.
- Biomarkers for dietary exposure are reflected in OTA levels in plasma, serum, urine and breast milk and overall levels in Europe have not changed since the last EFSA evaluation.
- Reliable biomarkers of OTA-specific effects, in particular on kidney function, have not been identified.

5.4. Toxicity in experimental animals and *in vitro*

- OTA exerts a variety of adverse effects in repeated dose studies in mice, rats, rabbits and pigs including immunotoxicity, neurotoxicity, developmental effects at maternally toxic doses. The critical effects occur in the kidney, the pig being the most sensitive animal species.
- Upon chronic oral exposure to OTA, increased incidences of kidney tumours have been observed in mice and rats, the rat being the most sensitive species.

- OTA induces gene mutations, DNA breaks and chromosomal damage of a specific type both *in vitro* and *in vivo*.

5.5. Observations in humans

- Possible associations between OTA exposure and kidney disease, bladder or hepatocellular cancer have been investigated in epidemiological studies, but it is not possible to establish a causal link between exposure to OTA and adverse effects in humans.
- The findings of raised protein concentrations in urine, indicative of impaired renal function, in a limited number of infants from Egypt exposed to high levels of OTA *via* their mothers (during pregnancy and lactation) raise concern and would need confirmation in larger studies.

5.6. Mode of action

- Multiple molecular events of OTA have been observed but the MoAs of OTA toxicity and renal carcinogenicity have not been clarified.
- Non-DNA reactive mechanisms play a role in OTA-induced kidney carcinogenesis. There is evidence that cycle arrest, induction of apoptosis and autophagy, alterations in cell proliferation, cell signalling, gene expression, redox homeostasis and epigenetic modifications as well as DNA and chromosomal damage may each contribute to tumour formation.
- The molecular mechanism underlying OTA genotoxicity remains unclear and it is not possible to conclude whether OTA causes DNA damage by indirect or direct effects.

5.7. Critical effects and derivation of reference points

- Increased incidence of microscopic kidney lesions seen in a repeated dose study with female pigs has been identified as the critical effect to be used for characterising non-neoplastic effects of OTA. A BMDL₁₀ of 4.73 µg OTA/kg bw per day derived from these effects was established.
- The increased incidences of kidney tumours seen in male rats in a 2-year study were identified as the critical effect for characterising neoplastic effects of OTA. A BMDL₁₀ of 14.5 µg OTA/kg bw per day derived from these effects was established.

5.8. Occurrence

- A total of 73,891 analytical results for OTA in food, respectively, fulfilled the quality criteria applied and from these 71,769 were selected and used in the assessment after grouping the categories and matching with the food consumption data.
- Current occurrence levels were similar to the ones in the previous assessment (EFSA, 2006) in case of foodstuffs where data were available that time. However, several new food categories were considered in the present assessment (e.g. other grain-based products, cheese, various meat products, tree nuts and dried fruits).
- The proportion of left-censored data was 75%, which resulted in a relatively big difference between the LB and UB occurrence values and exposure results.
- The highest mean concentrations of OTA were recorded in categories of 'Plant extract formula', 'Flavourings or essences' (both containing liquorice extracts) and 'Chili pepper'.

5.9. Exposure

- The mean exposure estimates ranged from 0.64 (minimum LB)/2.53 (minimum UB) to 9.13 (maximum LB)/17.79 (maximum UB) ng/kg bw per day across dietary surveys and age groups. At the 95th percentile, exposure estimates ranged from 2.40 (minimum LB)/5.13 (minimum UB) to 30.36 (maximum LB)/51.69 ng/kg (maximum UB) bw per day.
- The most important contributors to the chronic dietary exposure to OTA were 'Preserved meat', 'Cheese' and 'Grains and grain-based products'. Dried and fresh fruit such as grapes, figs and dates as well as fruit juices and nectars were also contributing to the exposure in some of the 'Toddlers' and 'Other children' groups, albeit, to a lesser extent than the three major categories. 'Non-chocolate confectionary' was a significant source of exposure in countries where liquorice-based sweets are commonly consumed.

- In a specific exposure scenario, occurrence data on OTA in breast milk from one study in the public literature were used, to assess the exposure of infants from breastfeeding.
- Based on a median concentration of OTA of 13 ng/L and a 95th percentile (P95) concentration of OTA of 43 ng/L in human milk, the chronic dietary exposure to OTA ranged from 1.7 to 5.6 ng/kg bw per day for infants with an average milk consumption and from 2.6 to 8.5 ng/kg bw per day for infants with a high milk consumption.

5.10. Risk characterisation

- Since the previous EFSA assessment (2006), more recent studies have raised uncertainty regarding the mode of action for kidney carcinogenicity. The CONTAM Panel considered it was not appropriate to establish a HBGV and concluded that for both non-neoplastic and neoplastic effects of OTA, an MOE approach needs to be applied.
- The TWI of 120 ng/kg bw as established by the CONTAM Panel in 2006 is no longer valid.
- For non-neoplastic effects, an MOE of 200 or higher between the selected RP and the estimated dietary exposures would be of low health concern.
- The calculated MOEs for non-neoplastic effects were above 200 in most of the dietary surveys for average and high consumers and therefore of low health concern.
- However, in high consumers of the age group of 'Infants', the MOEs were below 200 at maximum LB in 'Infants' and at maximum in 'Infants', 'Toddlers' and 'Other children', indicating a possible health concern for these age groups.
- The calculated MOEs for non-neoplastic effects were above 200 in all exposure scenarios for breastfed infants and thus of low health concern.
- Following EFSA guidance for substances that are both genotoxic and carcinogenic, an MOE of 10,000 or higher between the RP and the estimated dietary exposure would be of low health concern.
- The calculated MOEs for neoplastic effects in most of the surveys, in particular those for high consumers and for breastfed infants in all scenarios were below 10,000 and thus indicate a possible health concern for these consumer groups.
- In the interpretation of the MOE for the neoplastic risks, the Panel considered that the MOE of 10,000 for substances that are directly genotoxic and carcinogenic may not be appropriate in this case because the evidence for a direct interaction of OTA with the DNA is inconclusive.
- However, in the absence of elucidated MoAs for the genotoxicity/carcinogenicity of OTA, the Panel concluded that an MOE of 10,000 needs to be applied to the BMDL₁₀ of 14.5 µg/kg bw per day for neoplastic effects (kidney tumours) in the rat.

6. Recommendations

- More studies elucidating the sequence of critical events at the carcinogenic target site in the kidney are needed.
- More information on the specific signature of OTA gene mutations in appropriate animal models is needed
- More studies on the differential toxicokinetics of OTA in laboratory animals and humans are needed including transfer of OTA to the fetus.
- More studies relating biomarkers of exposure, i.e. OTA in plasma/serum, to external daily intakes are needed for more reliable estimates of OTA exposure.
- Reliable and representative investigations of the levels of OTA in human breast milk are needed.
- More occurrence data on OTA in cheese paste vs. cheese rind are needed.
- More data on occurrence and toxicity of modified OTA are needed.

Documentation provided to EFSA

Data on individual OTA concentrations in breast milk samples were kindly provided by Gisela Degen (Leibniz-Research Centre for Working Environment and Human Factors (IfADo), Dortmund, Germany) on 3 October 2019 (data from Muñoz et al., 2013); Filippo Rossi (Institute of Food Science and Nutrition, Faculty of Agriculture, Università Cattolica del Sacro Cuore, Piacenza, Italy) on 10 October 2019 (data from Biasucci et al., 2011); Carlo Brera and Barbara de Santis (Laboratory for Mycotoxins,

Istituto Superiore di Sanità, Rome, Italy) with the consent of the data owner AIC (Associazione Italiana Celiaca) on 17 October 2019 (data from Valitutti et al., 2018).

Abbreviations

8-OHdG	8-hydroxydeoxyguanosine
Ad293	Human embryonic kidney (cells)
ADME	absorption, distribution, metabolism and excretion
AFB ₁	Aflatoxin B ₁
AhR	Aryl hydrocarbon receptor
Akt	Protein kinase B
ALP	Alkaline phosphatase
ALT	Alanine aminotransferase
AP	Apurinic/apurimidinic
AryIS	Aryl synthetase
AST	aspartate transaminase
Atk	protein kinase B
ATM	ataxia telangiectasia mutated gene
BD ₁₀	Benchmark dose defined as a 10% increase over the background
BEA	Beauvericin
BEN	Balkan endemic nephropathy
BMD	Benchmark dose
BMDL ₁₀	Benchmark dose lower confidence limit for an extra cancer risk of 10%
BMDL ₀₅	Benchmark dose lower confidence limit for an extra cancer risk of 5%
BMDL _{1SD}	Benchmark dose lower confidence limit for an extra cancer risk of 1 standard deviation
BMDU ₁₀	Benchmark dose upper confidence limit for an extra cancer risk of 10%
BMDU ₀₅	Benchmark dose upper confidence limit for an extra cancer risk of 5%
BMDU _{1SD}	Benchmark dose upper confidence limit for an extra cancer risk of 1 standard deviation

BMR	Benchmark response
BrdU	Bromodeoxyuridine
BUN	blood urea nitrogen
bw	Body weight
CA	Chromosome aberrations
CAR	constitutive activated/androstane receptor
cdc2	Cell division control protein
CDK2	Cyclin dependent kinase 2
CGN	chronic glomerular nephropathy
CHK2	Checkpoint kinase 2
C _{inulin}	Inulin concentration
CHO	Chinese hamster ovary
CIN	Chronic interstitial nephropathy
CINI	CIN of unknown aetiology
CONTAM	Panel on Contaminants in the Food Chain
COT	Committee on Toxicology
CTN	citrinin
CYP	Cytochrome P450
DATA Unit	EFSA former EFSA Dietary and Chemical Monitoring Unit
DMBA	7,12-dimethyl benz[α]anthracene
DMSO	Dimethyl sulfoxide
DNA	Deoxyribonucleic acid
DSBs	Double strand breaks
EEC	European Economic Community
EGFR	Epidermal growth factor receptor
ELISA	Enzyme-linked immunosorbent assay
ELK	ETS domain containing protein
EndoIII	endonuclease III
ER	Endoplasmatic reticulum
ERK 1/2	extracellular signal-regulated kinase 1/2
ETS	E26 transformation specific
EU	European Union
f	female
FAO	Food and Agriculture Organization
FB ₁	Fumonisin B ₁
FD	fluorescence detection
FEEDAP	EFSA Panel on additives and products or substances used in animal feed
FEDIOL	Vegetable oil and protein meal industry association
Fpg	Formamido-pyrimidine-DNA glycosylase
GC	Gas chromatography
GD	Gestation day
GI	Gastrointestinal
GGT	γ -glutamyltranspeptidase
GLDH	Glutamate dehydrogenase
GPx	Glutathione peroxidase
GSH	Glutathione
GSSG	Glutathione disulfide
GSR	Glutathione reductase
GST	glutathione S-transferase
Hb	Haemoglobin
HBGV	Health-based guidance value
HCC	Hepatocellular cancer
HDAC	Histone deacetylase
HEK293	human embryonic kidney
HKC	Rat kidney proximal tubule cells
HNF4 α	Hepatocyte nuclear factor 4 alpha
HO-1	Heme oxygenase 1

hOR	human oxidoreductase
HO-OTA	Hydroxy ochratoxin
HPLC	High-performance liquid chromatography
HPLC-ECD	High-performance liquid chromatography with electrochemical detection
HPLC-FLD	High-performance liquid chromatography with fluorescence detection
IARC	International Agency for Research on Cancer
IC ₅₀	mean half maximum inhibitory concentration
IF	Immunofluorescence
IFN	Interferon
IGF	Insulin-like growth factor
IHKE	Immortalised human kidney epithelial (cells)
IKK	<i>IκB kinase</i>
IL	interleukin
i.p.	intraperitoneal
IPCS	International Programme on Chemical Safety
i.v.	Intravenous
IVM	<i>in vitro</i> maturation
JECFA	Joint FAO/WHO Expert Committee on Food Additives
JNK	JunN-terminal kinase
KIM-1	Kidney injury molecule-1
K _M :	Michaelis constant
LAP	leucine aminopeptidase
LB	Lower bound
LC-MS	Liquid chromatography coupled to mass spectrometry
LC-MS/MS	Liquid chromatography coupled to quadrupole tandem mass spectrometry
LC-FD	Liquid chromatography coupled to fluorescence detector
LD ₅₀	Lethal dose killing 50% of the animals
LDH	lactate dehydrogenase
LOD	Limit of detection
LOAEL	Lowest-observed-adverse-effect-level
LOEL	Lowest-observed- effect-level
LOQ	Limit of quantification
m	Male
MAPK	Mitogen activated protein kinases
MCV	mean corpuscular volume
MDA	malondialdehyde
MDCK	Madin Darby canine kidney (cell)
miRNA	micro RNA
ML	Maximum level
MMTV	mouse mammary tumour virus
MN	Micronuclei
mRNA	messenger RNA
MoA	Mode of action
MOE	Margin of exposure
MRP	multidrug resistant protein
MS	Mass spectrometry
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
NAC	N-acetyl-L-cysteine
NADPH	Nicotinamide adenine dinucleotide phosphate
NCRI	Negligible cancer risk intake
NfκB	Nuclear factor κB
NMR	Nuclear magnetic resonance
NOEL	no-observed-effect-level
NOAEL	no-observed-adverse-effect-level
Nrf2	Nuclear factor erythroid 2-related factor 2
NTD	neural tube defects
NTP	National Toxicology Programme

OAT	Organic anion transporters
OR	Odds ratio
OSOM	Outer stripe of the outer medulla
OTA	Ochratoxin A
OTalpha	Ochratoxin alpha
OTB	Ochratoxin B
OTC	Ochratoxin C
OTHQ	Hydroquinone
OTQ	Quinona
p53	tumour protein p53
P95	95 th percentile
PAH	p-aminohippuric acid
PCNA	Proliferating cell nuclear antigen
PCV	packed cell volume
PCT	proximal convoluted tubular
PDK	Phosphoinositide dependent kinase
PEPCK	phosphoenolpyruvate carboxykinase
PKC	protein kinase C
PND	Postnatal day
PPAR	peroxisome proliferator-activated receptor
PPB	Plasma protein binding
PTWI	Provisional tolerable weekly intake
PXR	Pregnane X receptor
RBC	Red blood cells
qPCR	quantitative polymerase chain reaction
RDW	red cell distribution
RNA	Ribonucleic acid
ROS	Reactive oxygen species
RTS	renal transplanted subjects
SCE	Sister chromatid exchange
SD	Standard deviation
SOD	Superoxide dismutase
SOP	Standard operating procedure
SSBs	Single strand breaks
SSD	Standard Sample Description
STER	Sterigmatocystin
TBARS	Thiobarbituric acid reactive substances
TCR	T-cell receptor
TD ₀₅	Tumorigenic dose 5%
TDI	Tolerable daily intake
<i>Tk</i>	Thymidin kinase
TK	Toxicokinetics
TIMP-1	Tissue inhibitor of metalloproteinase-1
TLC	Thin layer chromatography
TLC HPLC-UV	thin layer chromatography high-performance liquid chromatography with ultraviolet detection
Tm _{PAH}	Average maximal tubular excretion of PAH
Tm	Time to maximum concentration
TNF	Tumour necrosis factor
TopoII	Topoisomerase II
TPA	12-O- tetradecanoylphorbol-13-acetate
TWI	Tolerable weekly intake
UB	Upper bound
UCM-MSC	Canine umbelical cord matrix-mesenchymal stem cells
UDS	Unscheduled DNA synthesis
UF	Uncertainty factor
UGT	Uridine 5'-diphospho-glucuronosyltransferase (UGT)

UPLC	Ultra performance liquid chromatography
UPLC-Q/TOF-MS	ultra-high-performance liquid chromatography-quadrupole time-of-flight mass spectrometry
V79 cells	Chinese hamster lung cells clone V79
V_{\max}	maximum velocity of an enzymatic reaction
WG	working group
Wnt-1	Wingless -type MMTV integration site family, member 1
WHO	World Health Organization
wk	week

Appendix A – Identification and selection of relevant scientific literature and reports

Chemistry and Analysis	
Search terms	TOPIC: ochratoxin OR ochratoxin A OR OTA AND TOPIC: analys* OR determ* OR method* OR identif* OR character*
Numbers of papers found	4,882
Papers selected as potentially relevant	Not applicable
Formation Occurrence Exposure	
Search terms	TOPIC: ochratoxin OR ochratoxin A OR OTA AND TOPIC: occurrence OR expos* OR level* OR concentrat* OR formation OR food OR breast milk OR consump* OR foodstuff* OR diet*
Numbers of papers found	5,050
Papers selected as potentially relevant	Not applicable
Mode of Action	
Search terms	TOPIC: ochratoxin OR ochratoxin A OR OTA AND TOPIC: mode OR mechanis* OR mode of action OR mechanism of action
Numbers of papers found	1,052
Papers selected as potentially relevant	156
Toxicokinetics	
Search terms	TOPIC: ochratoxin OR ochratoxin A OR OTA AND TOPIC: toxicokinetic* OR metabolis* OR distribut* OR excret* OR absor* OR distribut* OR biotransform* OR eliminat* tissue OR kinetic*
Numbers of papers found	871
Papers selected as potentially relevant	37
Toxicity	
Search terms	TOPIC: ochratoxin OR ochratoxin A OR OTA AND TOPIC: toxic* OR tox* OR mutagen* OR carcino* OR genotox* OR aneugen* OR RNA OR reprotox* OR nephrotox* OR neurotox* OR hepatotox* OR immunotox* OR haemotox* OR hematotox* OR cytotox* OR develop* OR DNA* OR clastogen* OR cancer OR tumour OR tumor OR teratogen* OR rat OR mouse OR mice OR rabbit* OR in vitro OR in vivo OR muta* OR damage OR repair OR inhibit* OR chromosom* OR genetic* OR oxidative OR proliferation
Numbers of papers found	4,274
Papers selected as potentially relevant	254
Human evidence and biomarkers	
Search terms	TOPIC: ochratoxin OR ochratoxin A OR OTA AND TOPIC: biomarker OR biological marker OR case stud* OR poison* OR epidem* human* OR cohort OR case control OR cross-section*
Numbers of papers retrieved	157
Papers selected as relevant	27
Database used	Web of Science and PubMed
Time limit	2006–2018
Date of search	15/7/2018
Total number considered potentially relevant in sections Mode of action, toxicokinetics, toxicity and human evidence^(a)	451

(a): Note that there was a considerable overlap, i.e. many publications were found in more than one of the individual searches.

Appendix B – Evidence for protective effects of antioxidants and free radical scavengers against OTA-induced toxicity

Table B.1: *In vivo* evidence for protective effect of antioxidants/free radical scavengers against OTA

Test system	Protective agent	Results	Reference
Pre- or Co-treatment of rats after 4 weeks of OTA treatment	Melatonin	Inhibition of liver and kidney toxicity. Reduction of indicators of oxidative stress	Meki and Hussein (2001), Ozcelik et al. (2004), Abdel-Wahhab et al. (2005), Sutken et al. (2007)
Rats	Red wine	Inhibition of kidney toxicity. Reduction of oxidative damage	Bertelli et al. (2005)
Rats	2-mercaptoethane sulfonate (thiol)	Reduced karyomegaly but did not reduce the incidence of renal tumours	Pfohl-Leszkowicz and Manderville (2007)
Mice	<i>Emblica officinalis</i>	Prevented loss of DNA, RNA and protein from liver and kidney	Verma and Chakraborty (2008)
Mice	<i>Emblica officinalis</i>	Reduced lipid peroxidation in liver and kidney	Chakraborty and Verma (2010b)
Mice	Red wine	Reduced oxidative stress and DNA strand breaks in kidney	Cipriani et al. (2011)
Rats	Lycopene	Reduced liver and kidney DNA strand breaks	Aydin et al. (2013)
Rats	<i>Myricetin</i>	Reduced oxidative stress and kidney toxicity based on histopathology	El-Haleem et al. (2016)
Rats	Recombinant mitochondrial manganese containing superoxide dismutase	Prevention of hypertension and reduced glomerular filtration rate; prevention of renal and tubular degeneration	Ciarcia et al. (2016)
Rats	<i>Inulacrithmoides</i> extract	Reduced toxicity, reduced liver and kidney oxidative stress; reduced bone marrow micronuclei	Abdel-Wahhab et al. (2008)
Rats	Mitochondrial manganese containing superoxide dismutase	Prevented nephrotoxicity and reduced the loss of sodium reabsorption in kidney proximal tubules	Damiano et al. (2018a)
Rats	Delta-tocotrienol	Prevention of hypertension and reduced glomerular filtration rate and lowering of kidney antioxidant enzymes	Damiano et al. (2018b)

DNA: deoxynucleic acid; OTA: ochratoxin; RNA: ribonucleic acid.

Table B.2: *In vitro* evidence for protective effect of antioxidants/free radical scavengers against OTA

Test system	Protective agent	Results	Reference
Human hepatoma cells (HepG2)	Alpha-tocopherol, alpha-tocopherolphosphate, epigallocatechin gallate, quercetin, catechin and rosmarinic acid	No protection against cytotoxicity	Bösch-Saadatmandi et al. (2006)
Human proximal kidney tubule cells (HK-2)	N-Acetyl-L-cysteine	Reduction of reactive oxygen species and DNA strand breaks	Arbillaga et al. (2007)
Pretreatment of pig kidney cell line (LLC-PK1)	Epigallocatechin gallate and epicatechin gallate (antioxidant catechins)	Reduction of cell death, reactive oxygen and DNA fragmentation	Costa et al. (2007)
Gut epithelial cell line (Caco-2)	N-acetylcysteine	Protected against loss of claudins from membranes associated with tight junctions	Lambert et al. (2007)
Intestinal cells (Caco-2\TC7)	De-alcoholated Red wine	Increased tight junction permeability Increased relocation of claudin-4; Increased apoptosis	Ranaldi et al. (2007)
Bovine mammary epithelial cells; Porcine primary fibroblasts; Madin-Darby canine kidney cells (MDCK)	Alpha-tocopherol	Decreased apoptotic cell death	Fusi et al. (2008, 2010, 2018)
Human hepatoma cells (HepG2)	Ebselen or vitamin E	No protection against cytotoxicity	El Golli Bennour et al. (2009)
Human Caco-2\TC7 cells	Zinc chelation	Increased apoptosis and permeability of tight junctions (reversed by zinc supplementation)	Ranaldi et al. (2009)
Pig kidney cells (LLC-PK1)	Leontopodic acid pretreatment	Reduced production of reactive oxygen species but did not inhibit cytotoxicity	Costa et al. (2010)
Primary rat hepatocytes	Silibinin	Decrease in apoptotic cell death; decreased lipid peroxidation	Essid and Petzinger (2011), Essid et al. (2012)
Human peripheral blood mononuclear cells	N-acetylcysteine	Reduction of reactive oxygen, DNA damage, cell cycle G1 arrest and downregulation of CDK4 and cyclinD1	Liu et al. (2012)
Monkey kidney cells (Vero cell line)	Quercetin	Reduced apoptosis and oxidative stress Reduced DNA damage	Ramyaa and Padma (2013)
Madin-Darby canine kidney cells (MDCK)	Diosmetin flavonoid	Prevents ATP depletion	Poór et al. (2014)
Human embryonic kidney (HEK293) cells	N-acetylcysteine	Reduced reactive oxygen production; reduced loss of mitochondrial membrane potential; reduced loss of superoxide dismutase activity; reduced DNA strand breaks and cell cycle arrest	Yang et al. (2014)
Intestinal cells (Caco-2)	Resveratrol	Increased cytotoxicity without an increase in reactive oxygen species	Cano-Sancho et al. (2015)

Test system	Protective agent	Results	Reference
Vero cells, and lymphocytes <i>in vitro</i> and mice <i>in vivo</i>	Polyphenols (caffeic acid, luteolin and chlorogenic acid)	Reduction of cytotoxicity (chlorogenic acid and caffeic acid); inhibition of DNA strand breaks (caffeic acid and chlorogenic acid) and inhibition of micronucleation (chlorogenic acid)	Cariddi et al. (2015)
Human peripheral blood lymphocytes	Sodium copper chlorophyllin	Reduced cytotoxicity and reduced DNA damage	Domijan et al. (2015)
Porcine kidney cells (PK15)	Selenomethionine; overexpressed selenoprotein S	Reduced cytotoxicity (by selenomethionine, evidently via induction of glutathione peroxidase); Inhibition of promotion of viral replication (selenoprotein S)	Gan et al. (2015, 2016)
Human hepatoma cells (HepG2)	Vitamin E	Reduced cytotoxicity and reactive oxygen production	Gayathri et al. (2015)
Human embryonic kidney cells (HEK293)	Resveratrol	Reduced DNA strand breaks	Raghubeer et al. (2015)
Neuro-2a cells	N-acetylcysteine pretreatment	Protected against apoptotic cell death	Bhat et al. (2016)
Monkey kidney cells (Vero cell line)	Superoxide dismutase mimic (MnTnHex-2-PyP)	Decreased reactive oxygen concentration Decreased cytotoxicity	Costa et al. (2016)
Porcine kidney cells (PK-15)	N-acetylcysteine Selenomethionine	Reduced autophagy	Qian et al. (2017, 2018)

ATP: adenosin triphosphate; CDK4: Cyclin-dependent kinase 4; DNA: deoxyribonucleic acid; OTA; ochratoxin A; G1: Gap 1 phase.

Appendix C – Description of repeated dose studies already evaluated in previous assessments

C.1. Studies with rats

In Fischer 344/N rats administered OTA at 0, 21, 70, or 210 µg OTA /kg bw in corn oil by gavage (5 days per week) equivalent to 0, 15, 50 and 150 µg/kg bw per day for up to 2 years, increased incidences of neoplastic (kidney tubule adenoma and carcinoma) and non-neoplastic renal lesions involving degeneration of the renal tubular epithelium, proliferation of the tubular epithelium and karyomegaly were observed in kidney of male and female rats at 70 and 210 µg OTA/kg bw (NTP, 1989). No renal lesions were recorded at 21 µg OTA/kg bw (NTP, 1989). Thus, the NOAEL and LOAEL for OTA nephrotoxicity in Fischer 344/N rats were 21 and 70 µg OTA /kg bw per day, 5 days per week, respectively, equivalent to 15 and 50 µg/kg bw per day. In contrast, minimal renal changes consisting of eosinophilic granular or hyaline changes in proximal convoluted tubules were reported in a 90-day feeding study in Wistar rats (Munro et al., 1974). In this study, groups of male and female weanling Wistar rats were fed semi-purified diets containing 0, 0.2, 1 and 5 mg OTA/kg (Munro et al., 1974), equivalent to 0, 15, 75 and 37 µg OTA/kg bw (FAO/WHO, 2001), for 90 days. The authors of the study considered that these changes may present a phenomenon of ageing accelerated by OTA exposure (Munro et al., 1974). Based on this study, an (sensitive) LOAEL for OTA nephrotoxicity in Wistar rats of 15 µg OTA/kg bw was derived (FAO/WHO, 2001; EFSA, 2006).

Table C.1: Key studies with rats published before 2006

Strain	Dose and animals per group	Duration/time of observation	Main effects observed	Effect level	Reference
Wistar (♂, ♀)	0, 0.2, 1, 5 mg/kg feed (corresponding to 0, 15, 75, 37 µg/kg bw ⁽¹⁾)	90 days	<ul style="list-style-type: none"> Reduced relative kidney weight (1.5 mg/kg feed) Renal histopathological changes: Minimal renal changes consisting of eosinophilic granular or hyaline changes in proximal tubules (0.2 mg/kg feed); desquamation of proximal tubule cells (5 mg/kg feed), regenerative changes (all doses) 	LOAEL* 15 µg/kg bw per day ⁽¹⁾	Munro et al. (1974)
F344/N (♂, ♀)	0, 21, 70, 210 µg/kg bw (gavage, 5 days/week) ⁽²⁾ n = 50	2 years	<ul style="list-style-type: none"> Non-neoplastic renal lesions: degeneration of the renal tubular epithelium, proliferation of the tubular epithelium, karyomegaly (70 and 210 µg/kg bw) Increased incidence of kidney tubule adenoma and carcinoma (70 and 210 µg/kg bw) 	NOAEL* 21 µg/kg bw (5 days/week) ⁽³⁾ LOAEL* 70 µg/kg bw (5 days/week) ⁽⁴⁾	NTP (1989)

LOAEL: lowest observed adverse effect level; NOAEL: no observed adverse effect level.

(1): As estimated by FAO/WHO (2001).

(2): Equivalent to 0, 15, 50, 150 µg/kg bw per day.

(3): Equivalent to 15 µg/kg bw per day.

(4): Equivalent to 50 µg/kg bw per day.

*: NOAEL/LOAEL not explicitly reported by the authors of the study but derived from data presented in study.

C.2. Studies with pigs

In previous assessments, a series of studies in pigs was used to establish a HBGV (FAO/WHO, 1991, 1996, 2001, 2008; EFSA, 2006). These studies are briefly summarised below and presented in more detail in Table C.2.

Porcine nephropathy induced by administration of crystalline OTA for periods of 5 days, 3 months and 2 years was reported in a series of papers (Elling, 1979a,b; Krogh et al., 1979). Groups of female pigs (Danish Landrace) were daily administered gelatin capsules containing a crystalline OTA preparation (90% OTA and 5% OTB as determined by thin layer chromatography) at an average dose of 30–50 µg OTA/kg bw corresponding to a feed level of 1 mg/kg bw for 3 months (n = 3) or 2 years (n = 6) (Krogh et al., 1976, 1979). Control animals were given capsules containing lactose. Consistent with the previous study (Krogh et al., 1974), increased serum creatinine and urinary glucose accompanied by a decrease in Tm_{PAH} and Tm_{PAH}/C_{Inulin} and a decreased ability to concentrate urine were reported in animals administered OTA for 3 months. Microscopic lesions in kidneys consistent primarily of degenerative changes within the proximal tubule, tubular atrophy and interstitial fibrosis (Krogh et al., 1976). Using histochemical staining of kidney sections, changes in the enzymatic activity of NADH-tetrazolium reductase, succinate dehydrogenase, acid phosphatase and alkaline phosphatase within the pars convolute and/or pars recta of the proximal tubules were observed (Elling, 1979b). After 2 years exposure to OTA, essentially the same changes were evident as after 3 months, except that renal histopathological lesions were more widely distributed throughout the renal cortex (Elling, 1979b; Krogh et al., 1979). Terminal renal failure was not observed (Krogh et al., 1979).

In a subsequent study by the same group, renal enzyme activities were measured in needle biopsies obtained from kidneys of female pigs (Danish Landrace – Duroc) given gelatine capsules containing OTA equivalent to 0.2 and 1 mg OTA/kg feed for up to 5 weeks (Krogh et al., 1988). A dose-related decrease in the enzymatic activities of cytosolic phosphoenolpyruvate carboxykinase (PEPCK) and the brush boarder enzyme gamma-glutamyl transpeptidase accompanied by decrease in Tm_{PAH} and Tm_{PAH}/C_{Inulin} were observed (Meisner and Krogh, 1986; Krogh et al., 1988).

Table C.2: Studies in pigs used in previous assessments to establish HBGVs

Strain	Dose and animals per group	Duration/time of observation	Main effects observed	Effect level	Reference
Danish Landrace-Duroc (♀)	Gelatin capsules containing OTA equivalent to 0, 0.2 and 1 mg/kg feed, n = 6	1–5 weeks	<ul style="list-style-type: none"> Decrease in renal enzyme activities of PEPCK and gamma-GT (0.2 and 1 mg/kg feed) Decrease in Tm_{PAH} and Tm_{PAH}/C_{Inulin} (0.2 and 1 mg/kg feed) 	0.2 mg/kg feed (based on kidney lesions)	Krogh et al. (1988), Meisner and Krogh (1986)
Danish Landrace (♀)	0, 0.2, 1, 4 mg/kg feed (corresponding to ~ 8, 40, and 160 μ g/kg bw), n = 4–9	3–4 months (i.e. from 20 to 90 kg bw)	<ul style="list-style-type: none"> Increased water consumption & increased serum creatinine and urea (4 mg/kg feed) Increased urinary glucose, decreased reabsorption of glucose, decreased ability to concentrate urine, altered enzymatic activities of GLDH and LAP in renal cortex (1 and 4 mg/kg feed) Renal histopathological changes: tubule dilation with reduced brush boarder, pycnotic nuclei, mitotic figures, desquamation of tubule cells (0.2, 1 and 4 mg/kg bw), degenerative changes, glomerulosclerosis, interstitial fibrosis (1 and 4 mg/kg feed) Decreased Tm_{PAH} and Tm_{PAH}/C_{Inulin} (0.2, 1 and 4 mg/kg feed) 	0.2 mg/kg feed (corresponding to 8 μ g/kg bw) (based on kidney lesions)	Krogh et al. (1974)
Danish Landrace (♀)	0, 30–50 μ g/kg bw (gelatin capsule) (corresponding to 0 and 1 mg/kg feed), n = 3–6	3 months	<ul style="list-style-type: none"> Renal histopathological changes: proximal tubule degeneration, tubular atrophy, interstitial fibrosis Decreased Tm_{PAH}/C_{Inulin}; decreased ability to concentrate urine, increased urinary glucose Changes in renal enzyme activity of NADH-TR, SDH, ACP and ALP 	0, 30–50 μ g/kg bw (corresponding to 0 and 1 mg/kg feed) (based on kidney lesions)	Krogh et al. (1976, 1979), Elling (1979a, b)
		2 years	<ul style="list-style-type: none"> Renal histopathological changes: proximal tubule damage, tubular atrophy, interstitial fibrosis, hyalinised glomeruli Decreased Tm_{PAH} and Tm_{PAH}/C_{Inulin}; decreased ability to concentrate urine, increased glucose excretion Changes in renal enzyme activity of NADH-TR, SDH, ACP and ALP 	0, 30–50 μ g/kg bw (corresponding to 0 and 1 mg/kg feed) (based on kidney lesions)	Krogh et al. (1979), Elling (1979b)

ACP: acid phosphatase; ALP: alkaline phosphatase; GLDH: glutamate dehydrogenase; γ -GT: γ -glutamyl transpeptidase; LAP: leucine aminopeptidase; NADH-TR: NADH-tetrazolium reductase; OTA: ochratoxin A; PEPCK: cytosolic phosphoenolpyruvate carboxykinase; SDH: succinate dehydrogenase; Tm_{PAH} : average maximal tubular excretion of PAH; Tm_{PAH}/C_{Inulin} : ratio between Tm_{PAH} and average renal clearance of inulin.

Appendix D – Species differences regarding free and bound OTA

Calculations for the differences in the concentrations of free OTA in the blood plasma of humans, pigs and rats because of the different plasma protein binding (PPB) of OT (in particular to serum albumin, Alb), and the different accumulation.

Blood plasma levels of free (unbound) OTA in humans, pigs and rats assuming the same total concentration (free plus albumin-bound)

In general terms, the binding constant (or association constant, K_a) is the equilibrium constant for the binding of a ligand L to a receptor R according to the reaction $R + L \leftrightarrow RL$ and defined as $K_a = [RL]/[R] \times [L]$ (indicating the concentrations of R, L and RL at equilibrium).

In this case, K_a refers to the equilibrium $Alb + OTA \leftrightarrow Alb \times OTA$ and therefore

$$K_a = [Alb \times OTA]/[Alb] \times [OTA]$$

For the concentration of free (unbound) OTA: $[OTA] = [Alb \times OTA]/[Alb] \times K_a$

The following assumptions were made:

Total plasma levels of OTA (bound and unbound): 10 nanomolar (= 10^{-8} M, corresponding to the upper limit of normally exposed humans)

Concentration of albumin in the plasma of humans, pigs and rats: 600 micromolar (= 6×10^{-4} M)

Because of the large excess of Alb over OTA: $[Alb] = 6 \times 10^{-4}$ M at equilibrium

Because of the high binding: $[Alb \times OTA] = 10^{-8}$ M (virtually all the OTA is bound)

Binding of OTA to human albumin ($K_a = 5.2 \times 10^6$ M⁻¹):

$[OTA] = 10^{-8}$ M / 6×10^{-4} M $\times 5.2 \times 10^6$ M⁻¹ = 10^{-8} M / $31.2 \times 10^2 = 3.2 \times 10^{-12}$ M = 3.2 picomolar free OTA

9,997 picomolar bound OTA

Binding of OTA to pig albumin ($K_a = 7.1 \times 10^4$ M⁻¹):

$[OTA] = 10^{-8}$ M / 6×10^{-4} M $\times 7.1 \times 10^4$ M⁻¹ = 10^{-8} M / $42.6 \times 10^0 = 2.3 \times 10^{-10}$ M = 230 picomolar free OTA

9,770 picomolar bound OTA

Binding of OTA to rat albumin ($K_a = 4.0 \times 10^4$ M⁻¹):

$[OTA] = 10^{-8}$ M / 6×10^{-4} M $\times 4.0 \times 10^4$ M⁻¹ = 10^{-8} M / $24 \times 10^0 = 4 \times 10^{-10}$ M = 400 picomolar free OTA

9,600 picomolar bound OTA

Conclusion: At the same total plasma concentration of OTA in humans, pigs and rats, the plasma concentration of free OTA is more than 70-fold lower in humans than in pigs and 120-fold lower in humans than in rats.

Blood plasma levels of free (unbound) OTA in humans, pigs and rats taking into account the different accumulation at steady state (assuming the same bioavailability and rate of metabolism)

The free plasma concentration will be dependent on both the elimination half-life $t_{1/2}$ and free fraction

$$\text{Plasma conc} = \frac{\text{Intake} \times \text{bioavailability} \times t_{1/2}}{\ln 2}$$

$$\text{Free plasma conc} = \frac{\text{Intake} \times \text{bioavailability} \times t_{1/2}}{\ln 2} \times \text{free fraction}$$

The following free fractions and plasma elimination half-lives were used:

Human: 3.2×10^{-4} M, 35 days

Pig: 230×10^{-4} M, 5–6 days

Rat: 400×10^{-4} M, 5–6 days

Conclusion:

At the repeated intake of the same amount of OTA, given the same bioavailability and at steady state, the free fraction of OTA in human plasma is about 10 times lower than in the pig and 18 times lower than in the rat.

Appendix E – Studies on biotransformation of OTA

Table E.1: *In vitro* studies on biotransformation of OTA

Experimental system	Species	Purity of OTA	Metabolites	Analytical method	Structure confirmation	Comment	Reference
Liver microsomes	Rabbit, human, pig		4(R)-HO-OTA;4(S)-HO-OTA	TLC	MS, NMR	Enzyme kinetics ($V_{max} + K_M$)	Størmer et al. (1981)
Liver microsomes +/- phenobarbital	Rabbit	Not specified	4(R)-HO-OTA; 4(S)-HO-OTA; 10-HO-OTA	TLC HPLC-UV	MS, NMR	Enzyme kinetics ($V_{max} + K_M$)	Størmer et al. (1983)
Kidney cells (Vero cells)	Monkey	Not specified	OTalpha; 4(R)-HO-OTA; 4 (S)-HO-OTA; OTB	HPLC-FLD	–	No kinetics	Grosse et al. (1995)
Kidney microsomes +/- phenobarbital	Rabbit	Not specified	4(R)-HO-OTA; 4(S)-HO-OTA 10-HO-OTA; OTB; 3 unidentified metabolites	HPCL-FLD		No kinetics	El Adlouni et al. (2000)
Bronchial epithelial cells +/- phenobarbital	Human	Not specified	OTalpha; 4(R)-HO-OTA; 4 (S)-HO-OTA; 10-HO-OTA; OTB; 3 unidentified metabolites				
Liver microsomes +/- GSH and cytosol	Rat ♂♀	[U- ³ H]OTA (18 Ci/mmol) radiochemical purity > 98%	4(R)-HO-OTA	HPLC-radioactivity detector	MS, NMR	Enzyme kinetics (V_{max})	Gautier et al. (2001)
Liver microsomes +/- GSH and cytosol	Human		4(R)-HO-OTA			No evidence of GSH conjugates	
Liver S-9 +/- GSH	Rat		4(R)-HO-OTA			No evidence of GSH conjugates	
Kidney microsomes +/- GSH and cytosol	Rat, Human		–			No evidence of GSH conjugates	
CYP1A1, 1A2, 2E1, 3A4	Human		4(R)-HO-OTA				
CYP1A2, 2C11	Rat		–				
Seminal vesicle microsomes	Ram		Unidentified metabolite				
Seminal vesicle microsomes enriched in prostaglandin H-synthase Horseradish peroxidase			–				

Experimental system	Species	Purity of OTA	Metabolites	Analytical method	Structure confirmation	Comment	Reference
Liver microsomes +/- inducers of CYPs	Rat, mice ♂♀	> 99% (HPLC)	4(R)-HO-OTA; 4(S)-HO-OTA	HPLC-FLD	MS/MS	Enzyme kinetics ($V_{max} + K_M$)	Zepnik et al. (2001)
CYP1A2, 2C9-1, 3A4 supersomes ^{®1}	Human	> 99% (HPLC)	4(R)-HO-OTA; 4(S)-HO-OTA		MS/MS	Enzyme kinetics (V_{max})	
Semipurified GSTs +/- liver and kidney cytosol	Rat	> 99% (HPLC)	4(R)-HO-OTA; 4(S)-HO-OTA		MS/MS	Enzyme kinetics (V_{max})	
Kidney microsomes or cytosol fortified with NADPH and GSH; Liver cytosol	Rat	> 99% (HPLC)	–		–	–	
Horseradish peroxidase/ H ₂ O ₂ Soybean lipoxygenase	–	> 99% (HPLC)	–		–	–	
Primary hepatocytes +/- induction by 3-methylcholanthrene	Rat, human	³ H-OTA (0.6 Ci/mmol)	4(R)-HO-OTA; OTA-hexose OTA-pentose	HPLC-radioactivity detection/ quantification system	MS/MS	No effect of β-Gluc, sulfatase or GGT on metabolite retention times, suggesting that phase-II-conjugates were not formed	Gross-Steinmeyer et al. (2002)
Liver microsomes	Rat	Not specified	4-HO-OTA; OTHQ-GSH	LC-MS/MS		OTHQ-GSH generated in less than 1% yield	Dai et al. (2002)
Horseradish peroxidase/ H ₂ O ₂			–				
Fe ₂ (NH ₄) ₂ (SO ₄) ₂ /H ₂ O ₂			OTHQ-GSH				
Kidney cells	Opossum	Not specified	OTalpha; 4(R)-HO-OTA 4(S)-HO-OTA; OTB; OTHQ; OP-OTA; Several unidentified metabolites	HPLC-FLD nano-ESI-IT-MS		No kinetics	Faucet-Marquis et al. (2006)

Experimental system	Species	Purity of OTA	Metabolites	Analytical method	Structure confirmation	Comment	Reference
Liver microsomes	Rat, human, pig, cow, chicken, goat	99%	4(R)-HO-OTA; 4(S)-HO-OTA Hydroxylated metabolites tentatively identified as 9'-HO-OTA; 7'-HO-OTA, 5'-HO-OTA; OTB	UPLC-Q/TOF-MS		No enzyme kinetics No OTA-derived glucuronides detected	Yang et al. (2015)

GGT: γ -glutamyltranspeptidase; β -Gluc: β -glucuronidase; GSH: glutathione; HO-OTA: hydroxy ochratoxin; HPLC-FLD: high-performance liquid chromatography with fluorescence detection; K_M : Michaelis constant, concentration of substrate which permits the enzyme to achieve half V_{max} ; NADPH: nicotinamide adenine dinucleotide phosphate; OTA: ochratoxin A; OTalpha: ochratoxin alpha; OTB: ochratoxin B; OTHQ: ochratoxin hydroquinone; LC-MS/MS: liquid chromatography-mass spectrometry and tandem mass spectrometry; MS: mass spectroscopy; nano-ESI-IT-MS: thin layer chromatography-quadrupole time-of-flight mass spectrometry; TLC HPLC-UV: thin layer chromatography high-performance liquid chromatography with ultraviolet detection; UPLC-Q/TOF-MS: ultra-high-performance liquid chromatography-quadrupole time-of-flight mass spectrometry; V_{max} : maximum velocity of an enzymatic reaction.

(1): Corning Supersomes[®] enzymes are recombinantly expressed drug metabolising enzyme reagents, consisting of microsomes prepared from insect cells infected with a virus engineered to express a CYP isoform.

Table E.2: *In vivo* studies on biotransformation of OTA in rats

Strain/sex	Treatment regimen	Purity of OTA	Specimen analysed	Metabolites	Analytical method	Comment	Reference
Wistar rats ♂	15 mg/kg bw; single oral dose; ¹⁴ C-OTA labelled inisocoumarin moiety	Not specified	Urine, faeces	OTalpha	TLC- Liquid scintillation counting		Suzuki et al. (1977)
Sprague Dawley rats ♂	2.7 mg/kg bw; single <i>i.v.</i> dose; ¹⁴ C-OTA uniformly labelled	96% radio-chemical purity (TLC)	Urine, faeces	OTalpha; 5 unidentified metabolites	TLC- Autoradiography		Galtier et al. (1979)
Albino rats ♂	6.6 mg/kg bw; single oral or <i>i.p.</i> dose	Not specified	Urine, faeces	OTalpha; 4(R)-HO-OTA	TLC-UV	Confirmation of OTalpha by MS	Støren et al. (1982)
Sprague Dawley rats ♂	4 mg/kg bw; single <i>i.p.</i> dose	Not specified	Urine	OTalpha; 4(R)-HO-OTA; 2 unidentified metabolites	HPLC-FLD	OTB and OTB-derived metabolites not detected	Xiao et al. (1996)
Dark agouti rats ♀; Lewis rats ♀	0.5, 2.5, 5 mg/kg bw single dose; 1.5 mg/kg per day repeated oral dose for 8 weeks (5 days/week)	Not specified	Urine	4(R)-HO-OTA	HPLC-FLD		Castegnaro et al. (1989)
Sprague Dawley rats ♀	~ 333 µg/kg bw single <i>i.v.</i> dose	Not specified	Urine, bile	OP-OTA; 2 unidentified metabolites	HPLC-FLD		Li et al. (2000)
F344 rats ♂	1 mg/kg bw; single oral dose 40-55 µCi of [³ H] OTA uniformly labelled	> 98% radiochemically pure	Urine, faeces	OTalpha; 2 unidentified metabolites	HPLC-radioactive detector	Unknown metabolites did not correspond to OP-OTA, 4(R)-OH-OTA or OTB	Gautier et al. (2001)
F344 rats ♀♂	0.5 mg/kg bw; single oral dose	99,99% (HPLC-FLD)	Liver, kidney plasma, urine, faeces	OTalpha; OTA-hexose OTA-pentose	HPLC-FLD; LC-MS/MS	4(R,S)-OH-OTA, 10-OH-OTA, OTB, OTHQ and OTA derived GSH conjugates and glucuronides not detected	Zepnik et al. (2003)

Strain/sex	Treatment regimen	Purity of OTA	Specimen analysed	Metabolites	Analytical method	Comment	Reference
F344 rats ♂	2 mg/kg bw per day; repeated oral dose for 2 weeks (5 days/week)	99% (HPLC-FLD); Impurities: OTB (LC-MS/MS)	Liver, kidney plasma, urine, faeces	OTalpha; OTA-hexose; OTA-pentose	LC-MS/MS	Traces of OTB and a hydroxylated metabolite (presumably 4-OH-OTB (Mally et al., 2005c)) initially suggested to present OTHQ detected in urine. Authors consider this due to OTB present as impurity in OTA used to treat animals	Mally et al. (2004), personal communication, Angela Mally, University of Würzburg
Dark agouti rats ♀♂	100 µg/kg diet	Not specified	Lung, liver, kidney	OTalpha; OTB-GSH OTHQ-GSH	HPLC-FLD		Tozlovanu et al. (2012)
Sprague-Dawley rats ♂	0.2 mg/kg bw; single oral dose	Not specified	Plasma, liver, heart, spleen, lung, kidney, brain	OTbeta, phenylalanine, OTB-methyl ester	LC-MS/MS; LC-TOF-MS	OTalpha not detected; OTB not detected; OTA used to treat animals did not contain OTbeta or phenylalanine, presence of OTB not specified	Han et al. (2013a)
Wistar rats ♀♂	5 mg/kg bw; single oral dose	99%		4(R)-HO-OTA,4(S)-HO-OTA; Hydroxylated metabolites tentatively identified as 9'-HO-OTA, 7'-HO-OTA, 5'-HO-OTA OTB	UPLC-Q/TOF-MS	No OTA-derived glucuronides detected No synthetic reference compounds to support the chemical structure of metabolites	(Yang et al., 2015)

GSH: glutathione; HO-OTA: hydroxy ochratoxin; HPLC-FLD: high-performance liquid chromatography with fluorescence detection; OTA: ochratoxin A; OTalpha: ochratoxin alpha; OTB: ochratoxin B; OTbeta: ochratoxin beta; OTHQ: ochratoxin hydroquinone; LC-MS/MS: liquid chromatography-mass spectrometry and tandem mass spectrometry; MS: mass spectroscopy; nano-ESI-IT-MS: TLC: thin layer chromatography; TLC HPLC-UV: thin layer chromatography high-performance liquid chromatography with ultraviolet detection; UPLC-Q/TOF-MS: ultra-high-performance liquid chromatography-quadrupole time-of-flight mass spectrometry; V_{max} : maximum velocity of an enzymatic reaction.

Table E.3: Studies on biotransformation products of OTA in humans

Human	OTA exposure	Specimen analysed	Metabolites	Analytical method	Comment	Reference
Families affected by Balkan endemic nephropathy ♀♂	Unknown	Urine		HPLC-FLD	OTA present; 4-OH-OTA not detected	Castegnaro et al. (1991)
Human volunteer ♂	395 ng ³ H-OTA, uniformly labelled (3.8 µCi); radiochemical purity > 98%	Urine, plasma	42–54% of radioactivity in urine coeluted with OTA standard 14–20% of radioactivity in urine suggested to present metabolite (s) of smaller size or higher polarity than OTA	HPLC-FLD; Liquid scintillation counting of 2-min HPLC fractions		Studer-Rohr et al. (2000)
Volunteers from Portugal ♀♂	Unknown	Urine	Indirect evidence for OTA-derived glucuronide	HPLC-FLD +/- enzymatic cleavage of conjugates by β-Gluc	Structure of OTA-glucuronide not identified	Pena et al. (2006)
Healthy volunteers from Germany ♀♂	Unknown	Urine, plasma	OTalpha; Indirect evidence for OTalpha-conjugates	HPLC-FLD +/- enzymatic cleavage of conjugates by β-Gluc/AryIS	OTA glucuronide not detected Structure of OTalpha-conjugates not identified (e.g. OTalpha-glucuronide or OTalpha-sulfate)	Muñoz et al. (2010)
Volunteers from Spain ♀♂	Unknown	Urine	OTalpha	HPLC-FLD		Coronel et al. (2011)
Pregnant women from Croatia	Unknown	Urine	OTalpha; indirect evidence for OTalpha-conjugates	HPLC-FLD +/- enzymatic cleavage of conjugates by β-Gluc/AryIS	Structure of OTalpha-conjugates not identified (e.g. OTalpha-glucuronide or OTalpha-sulfate)	Klapec et al. (2012)
Breastfed infants from Germany and Turkey; German adults ♀♂	Unknown	Urine	Indirect evidence for OTA-conjugates in Turkish infants and German adults	HPLC-LC-MS/MS +/- enzymatic cleavage of conjugates by β-Gluc/AryIS	Proposed to represent OTA-8-β-glucuronide but structure of OTA-derived conjugates in urine needs yet to be confirmed	Muñoz et al. (2017)
German adults ♀♂	Unknown	Urine	OTB-NAC	LC-MS/MS		Sueck et al. (2019)

AryIS; Aryl synthetase; β-Gluc: β-glucuronidase; HO-OTA: hydroxy ochratoxin; HPLC-FLD: high-performance liquid chromatography with fluorescence detection; HPLC-LC-MS/MS: high-performance liquid chromatography liquid chromatography tandem mass spectrometry; OTA: ochratoxin A; OTalpha: ochratoxin alpha; OTB: ochratoxin B; OTB-NAC:OTB N-acetyl-L-cysteine; OTHQ: ochratoxin hydroquinone; LC-MS/MS: liquid chromatography-mass spectrometry and tandem mass spectrometry; MS: mass spectrometry; TLC HPLC-UV: thin layer chromatography high-performance liquid chromatography with ultraviolet detection; UPLC-Q/TOF-MS: ultra-high-performance liquid chromatography-quadrupole time-of-flight mass spectrometry.

Appendix F – BMD analyses

F.1. BMD analysis of microscopic kidney lesions in female pigs (Krogh et al., 1974)

A) Data Description

The endpoint to be analysed is: animals with microscopic kidney lesions.

B) Data used for analysis

$\mu\text{g OTA/kg bw per day}$	Number of animals with microscopic kidney lesions	Total number of animals
0	0	9
8	4	9
40	9	9
160	4	4

C) Selection of the BMR

The benchmark response (BMR) used is an extra risk of 10%.

The benchmark dose (BMD) is the dose corresponding to the BMR of interest.

A 90% confidence interval for the BMD will be estimated, with lower and upper bound denoted BMDL and BMDU, respectively.

D) Software Used

Results are obtained using the EFSA web-tool for BMD analysis, which uses the R-package PROAST, version 66.40, for the underlying calculations.

E) Results

Response variable: animals with microscopic kidney lesions

Fitted Models

J) Visualisation

F.2. BMD analysis of combined incidence of adenoma and carcinoma in male rats (NTP, 1989)

A) Data Description

The endpoint to be analysed is incidence kidney adenoma and carcinoma.

B) Data used for analysis:

μg OTA/kg bw per day	Incidence of kidney adenoma and carcinoma	N
0	1	50
15	1	50
50	20	51
150	36	50

C) Selection of the BMR

The BMR used is an extra risk of 10% compared to the controls.

The BMD is the dose corresponding with the BMR of interest.

A 90% confidence interval for the BMD will be estimated, with the lower and upper bound denoted BMDL and BMDU, respectively.

D) Software Used

Results are obtained using the EFSA web-tool for BMD analysis, which uses the R-package PROAST, version 66.40, for the underlying calculations.

E) Results

Response variable: incidence of kidney adenoma and carcinoma

Fitted Models

Annex – Summary statistics on occurrence and consumption data and exposure assessment results

The Annex is provided as separate Excel files containing summary statistics on occurrence and consumption data and exposure assessment results on ochratoxin A and is available on the EFSA Knowledge Junction community on Zenodo at: <https://doi.org/10.5281/zenodo.3739292>

At the zenodo link above, we have also included the occurrence data of OTA - please see Section 4.7 Occurrence data.
