ABSTRACT:

Reducing carbon dioxide emissions is one of the possible solutions to prevent global climate change, which is urgently needed for the sustainable development of our society. In this work, easily available, biodegradable amino acid ionic liquids (AAILs) with great potential for CO₂ absorption in the manned closed space such as spacecraft, submarines and other manned devices are used as the basic material. Molecular dynamics simulation and ab initio calculation methods were performed for 12 AAILs ([P4444][X] and [P66614][X], [X]= X=[GLy]⁻, [Im]⁻, [Pro]⁻, [Suc]⁻, [Lys]⁻, [Asp]²⁻), the dynamic characteristics and the internal mechanism of AAILs to improve CO₂ absorption capacity were clarified. Based on the analysis of structural and the interaction energy including van der Waals and electrostatic interaction, revealed the fact that the anion of ionic liquids dominates the interaction between CO₂ and AAILs. At the same time, the CO₂ absorption capacity of AAILs increases in the order: [Asp]²⁻ < [Suc]⁻ < [Lys]⁻ < [Pro]⁻ < [Im]⁻ < [Gly]⁻. Meanwhile, the synergistic absorption of CO₂ by multiple-site of amino and carboxyl groups in anion was proved by DFT calculation. These findings show that the anion of AAILs can be an effective factor to regulate the CO₂ absorption process, which can also provide guidance for the rational and targeted molecular design of AAILs for CO₂ capture, especially in the manned closed space.

KEYWORDS: Ionic liquids, CO₂ absorption, Molecular dynamics simulation, manned closed system.

1. Introduction

With the burning of fossil fuels, excessive emissions of CO₂ caused by automobile emissions and human activities, global warming and ecosystem changes have become one of the most serious challenges of environmental problems.¹⁻³ As a rich, non-toxic, and easily available renewable carbon resource, CO₂ has a wide range of applications in the fields of the chemical industry, oil and gas exploration, agriculture, tobacco, and firefighting. Separation and absorption of CO₂ have become a hot topic of common concern in academia, industry, and the international community.^{4,5} At present, traditional CO₂ absorption methods include adsorption and membrane separation, *etc.*, all of which are realized by using effective absorption materials and solvents.^{6,7} Therefore, the absorption performance of CO₂ is closely related to the development and selection of absorption materials and solvents.

As a new type of green solvent and medium, ionic liquids (ILs) is an alternative to traditional organic solvent, because of its unique properties such as high thermal stability, low melting point, wide electrochemical window, and adjustable structures, *etc.*^{8,9} In recent years, a large number of experimental and theoretical studies have reported that ILs can be used as solvents to effectively absorb CO₂ through traditional absorption and adsorption methods.¹⁰⁻¹² Wang *et al.*¹³ developed a novel integrated system consisting of the imidazolium-based ILs and organic superbase for the absorb of CO₂ under atmospheric pressure. The results have shown that the integrated system could quickly, effectively, and reversibly absorb about one mole of CO₂ per mole of ILs. In another study, an imidazole-ring functionalized copolymer for CO₂ separation were synthesized by Lee *et al.*¹⁴ They investigated the solubility and permeability of CO₂. Their findings showed that the excellent CO₂ separation performance was achieved by this material, with a CO₂ permeability of 148.6 Barrer and CO₂/N₂ and CO₂/CH₄ selectivity of 65.3 and 35.0, respectively. These conventional ILs and ILs-based materials have been proven to have many outstanding effects in CO₂ absorb; however, most of the researches are based on open spaces currently. Due to the harsh experimental conditions in enclosed spaces, there are few studies on the absorb of CO₂ in manned closed systems such as spacecraft and submarines. Therefore, the development of new solvents and materials with low energy consumption, high cycle stability and no by-products is a key challenge in the field of gas absorption in confined spaces.

Amino acids are environmentally friendly and biodegradable agents and contain no halide ions. Amino acid ionic liquids (AAILs), a novel type of ILs with a primary amine (–NH₂) functional group which are synthesized using natural amino acids as raw materials.^{15,16} Similar to conventional ILs, AAILs also has the characteristics of conventional ILs.¹⁷ Meanwhile, AAILs have many unique properties such as low toxic, strong biocompatibility, biodegradable and hydrogen bond network structure, which can dissolve many living substances, such as DNA, cellulose, carbonyl compounds, *etc.* Ohoo *et al.* synthesized AAILs from

20 kinds of natural amino acids for the first time in 2005.¹⁸ By analyzing the acidity, hydrogen bonding ability and steric factors of amino acids, they showed the importance of amino acid side groups on the properties of AAILs. After that, many studies have reported that compared with conventional ILs, AAILs can absorb CO₂ more effectively.^{19,20} Moghadam *et al.*²¹ separated the low concentration of CO₂ from the mixtures of CO₂/N₂ using the AAIL-based membrane. Their work indicated AAIL-based membrane showed high CO₂ permeability, is around 52000 bar, and high CO₂/N₂ selectivity, is around 8100. Seyedhosseini *et al.*²² conducted computational studies on the absorption of CO₂ by N7, N9-dimethyladeninium cation with amino acid anions ([dMA][X] X= Gly, Ala, Val, Leu, and Ileu). They found that an increase in the length of amino acid side chains increases the ability to absorb of CO₂. Recently, Kang *et al.* analyzed the CO₂ absorption mechanism of dual amino group functionalized imidazolium AAILs by ¹³C NMR and FT-IR spectroscopy. Their work indicated that the number of amino groups in the ILs affects their CO₂ absorption capacity.²³ Meanwhile, Shaikh *et al.*¹⁵ Using density functional theory (DFT) and molecular dynamics methods to study the reaction mechanism of tetramethylphosphonium glycinate ([P₁₁₁₁][Gly]) and tetrabutylphosphonium glycinate ([P₄₄₄₄][Gly]) AAIL to absorb CO₂, and the effect of AAILs on CO₂ adsorption in the presence of pure AAIL form and explicit water was explored. The results show that in the presence of water, the interaction between cations and anions decreases, thereby reducing the diffusion coefficient of cations, while in the presence of 10% water, the viscosity of the compound increases, thereby reducing carbon dioxide absorption. At the same time, it was found that the lower free volume and higher density produced in [P₁₁₁₁] [Gly] will inhibit the absorption of CO₂. At the same time, different from the traditional closed space absorb CO₂ methods (including non-renewable²⁴, physicochemical regeneration, and solid material-based adsorption methods²⁵), AAILs are bio-renewable and have potential advantages and application feasibility in the field of CO₂ absorb in manned closed system.

To design and choose appropriate ILs for carbon absorb, it is important to understand their properties and molecular interactions involved in the corresponding processes. Fundamental molecular insights are useful for understanding the thermodynamic, structural, physicochemical, and dynamic behaviors of AAILs. However, so far, there are few systematic theoretical studies on CO₂ absorb using AAILs. Moreover, most studies lack detailed discussions on "how the cations and anions of AAIL affect the physical and chemical properties of the gas liquid system" and "what role does AAILs play in capturing CO₂ molecules". To do this, we conducted MD simulations and the DFT to examine the effect of 12 types of tetrabutylphosphonium-based and trihexyltetradecylphosphonium-based AAILs (*viz.* [P₄₄₄₄][X] and [P₆₆₆₁₄][X], X=[Gly], [Im], [Pro], [Suc], [Lys], [Asp]) on CO₂ absorb. The physicochemical and dynamics properties of these AAILs-CO₂ systems, such as density, self-diffusion coefficient and residence time were calculated. Further the microstructures of AAILs were analyzed in various AAILs-CO₂ by

evaluating the radial distribution function ($g(r)$), spatial distribution function (SDF), and ionic coordination number (N). Meanwhile, van der Waals and coulombic energy between CO₂ and AAILs and the stable absorption site were explored by DFT analysis. Our current study will help to understand the reaction mechanism that will serve as a guide to design new ionic liquids with improved CO₂ absorb capability in manned closed system.

2. Simulation Details

2.1 Molecular Dynamics Simulations

All the MD simulations in this work were conducted for 512 CO₂ molecules in a periodic boundary box containing 512 pair of tetrabutylphosphonium-based and trihexyltetradecylphosphonium-based AAILs (*viz.* [P₄₄₄₄][X] and [P₆₆₆₁₄][X], X=[Gly], [Im], [Pro], [Suc], [Lys], [Asp]) at 300K, 350K and 400K (Figure 1). The all-atom optimized potential for liquid simulations force field (OPLS-AA) was used to describe the atom types for all-atom types in our MD simulations. The partial charges of CO₂ and AAILs were obtained by the restrained electrostatic potential (RESP) procedure.^{26,27} The initial configurations of the MD simulations were constructed by using the Packmol package.²⁸ All the MD simulations were carried out in the Lammmps software.²⁹ The Verlet algorithm is employed to integrate Newton's equations of motion which the time step is 1.0 fs. Meanwhile, the van der Waals interaction and the electrostatic interaction are treated with the Lennard-Jones potential and the Particle Mesh Ewald (PME) technique, respectively. For each simulation system is relaxed in the canonical ensemble (NVT) and the isothermal-isobaric ensemble (NPT) for the first 4ns. The production simulation in the NPT ensemble is carried out for 20ns and in the NVT ensemble to achieve the configurational equilibria for 30 ns. The trajectories are recorded at every 0.1ps for further analysis during the simulation.

2.2 Ab Initio Calculations

The structures for all the cations and anions of AAILs, and CO₂ were optimized at the B3LYP/6-311++G** level by Gaussian 09 software.³⁰ For anion-CO₂, the typical configuration in the MD trajectory is randomly selected as the initial structure. After optimization, 15 types of lower energy anion-CO₂ structures were selected on the B3LYP/6-311++G** level through Gaussian 09 software for further optimization. Then, the structure with the lowest energy and no imaginary frequency was obtained.

Figure 1. Structures of the AAILs involved in our MD simulations.

3. Results and Discussions

3.1 Liquid Density

In this work, the CO₂-AAILs density can be obtained in the equilibrium simulation of the 20ns NVT ensemble. The density of all AAILs and CO₂-AAILs at 300K was calculated and listed in (Table 1) in which the experimentally measured densities of the pure AAILs are also reported. Clearly, it is found that for a common anion, [P₄₄₄₄]⁺-type AAILs has a higher density than the [P₆₆₆₁₄]⁺-type AAILs, except for [Asp]²⁻ system, while for a common cation ([P₄₄₄₄]⁺ or [P₆₆₆₁₄]⁺), [Im]⁻-type AAILs have the lowest density in all systems. The results show that the size of the cation/anion of AAILs can affect the density of CO₂-AAILs system, *viz.*, the density decreases with the increased size of cation, on the contract, an opposite effect was observed for the anion of AAILs. The same conclusion was also reported by Sedden *et al.*³¹ Meanwhile, regardless of the type of cation, the [Asp]⁻-type system has the highest density for the amino acid anion type. It reflects a fact that the carboxyl groups(-COOH) and the number of carboxyl groups have an important influence on the density of the CO₂-AAILs system. Due to the addition of carboxyl groups, the interaction between carboxyl groups and CO₂ will increase, which will lead to an increase in system density. (The interaction will be discussed in detail below). Meanwhile, the density of the chain-type amino acid anion corresponding to the CO₂-AAILs system is slightly greater than that of the cyclic-type anion, which the order of the density for [P₆₆₆₁₄]⁺-type AAILs is [Asp]⁻>[Lys]⁻>[Gly]⁻>[Pro]⁻. Additionally, the simulated density of the pure AAILs for simulated values is higher than that of the experimental values, which is consistent with the typical deviation of the MD simulation allowed (*i.e.*, less than 3%). Since under the AA force field, the long chain of cations increases the influence of polarizability of AAILs, which tends to produce higher density. However, this work focuses on the absorption behavior of CO₂ in AAILs. In future

work, we will improve the force field and increase the accuracy of liquid density by carefully adjusting certain parameters or increasing the influence of the polarization rate.

Table 1. Experimental and simulated density (unit: g/cm³) of all CO₂-AAILs and pure AAILs systems.

Cation	Anion	$\rho_{sim-co2/AAILs}$	$\rho_{sim-AAILs}$	$\rho_{exp-AAILs}$ ^{32,33}	Error (%)
[P ₄₄₄₄] ⁺	[Gly] ⁻	0.94	0.93	0.96	2.67
	[Pro] ⁻	0.96	0.96	0.99	2.78
	[Im] ⁻	0.92	0.91	--	--
	[Lys] ⁻	0.96	0.95	0.97	1.64
	[Asp] ²⁻	0.99	--	--	--
	[Suc] ⁻	1.02	--	--	--
[P ₆₆₆₁₄] ⁺	[Gly] ⁻	0.91	0.89	0.90	0.81
	[Pro] ⁻	0.90	0.89	0.89	0.08
	[Im] ⁻	0.88	0.88	0.88	0.82
	[Lys] ⁻	0.93	--	--	--
	[Asp] ²⁻	1.04	--	--	--
	[Suc] ⁻	0.92	--	--	--

3.2 Dynamics behaviors

3.2.1 Diffusion Property

A high self-diffusion rate can improve the rate of absorption of CO₂ by AAILs. Therefore, the self-diffusion coefficient (D) of the anion/cation of AAILs and CO₂ in the CO₂-AAILs system was calculated according to Einstein's equation, which is a function of the ion mean square displacement (MSD) in the system, as given in equation (1):

$$D = \frac{1}{6} \lim_{t \rightarrow \infty} \frac{d}{dt} \langle \sum_{i=1}^N [\vec{r}_i(t) - \vec{r}_i(0)]^2 \rangle \quad (1)$$

where $\vec{r}_i(t)$ indicates the positional vector of the center of mass of the i th ion at a given time t . Meanwhile, to distinguish the different time scales, the exponent β can be computed over a range of time scales using

$$\beta = \frac{d \log(\Delta r^2(t))}{d \log(t)} \quad (2)$$

To our best knowledge, at short times the motions of the ions are almost ballistic movement, so that $\beta > 1$. At long times after the molecules have undergone many collisions the systems should become normal linear diffusive behavior, and $\beta = 1$. In the intermediate-time range, the motion shows subdiffusive dynamics similar to a supercooled liquid, which is related to cage escape, and $\beta < 1$.³⁴ Therefore, in this work, the effect of CO₂ absorption on AAIL cation and anion dynamics was examined by mean MSD for all systems over the time interval (t) from the last 10 ns on NVT ensemble of MD trajectory, then the slope of the MSD- t plots for the time corresponding to $\beta \approx 1$ were linearly fitted (dotted line in Figure 2(a)). The self-diffusion coefficients of cation, anion for all AAILs and CO₂ have been obtained and shown in Table 2.

Figure 2. (a) The plots of mean square displacement (MSD) of [P₄₄₄₄]⁺, [Asp]²⁻ vs. simulation time (t) in the [P₄₄₄₄][Lys]-CO₂ system. (b) The residence time for CO₂-anion in all systems.

Comparing the CO₂-AAILs systems with different cations in Table 2, it is obvious that for the same type of anion, the self-diffusion coefficient of CO₂ in the [P₆₆₆₁₄]⁺-type AAIL system is much higher than that of the [P₄₄₄₄]⁺-type (except for [P₆₆₆₁₄][Suc]), as evidenced by the self-diffusion coefficient in Table 2. This phenomenon is opposite of density, where CO₂ diffuses faster in a large size of cation systems. The same conclusion has also been proved in different ILs. For example, Ren *et al.* investigated the different alkyl chain lengths of imidazole cations with the anion ([TF₂N]⁻). It is found that the diffusion and solubility of CO₂ increase with the increased of cation length.³⁵ At the same time, due to the anion has a stronger coordination with the surrounding CO₂ molecular, the anion exhibits faster mobility than the cation in the

[P₆₆₆₁₄][X] systems ([X]=[Gly], [Im], [Pro], [Suc], [Lys], [Asp]) (The coordination number of cation and anion in AAILs will be discussed in detail later in the text). The same conclusions were drawn by Prakash *et al.*³⁶ in their simulation study of the [P₄₄₄₄] [Lys]-CO₂ system. Meanwhile, regardless of the AAIL cation type, the self-diffusion coefficient of CO₂ has the largest value in [Asp]²⁻-type AAIL, which is consistent with the results found in the density. In addition, for the amino acid-type anion of both [P₄₄₄₄]⁺-type and [P₆₆₆₁₄]⁺-type AAIL, the order of the self-diffusion coefficient of CO₂ follows: [Asp]²⁻>[Gly]⁻>[Pro]⁻>[Lys]⁻. That is to say, for chain-type amino acid anions, the rate of CO₂ movement decreases as the increased of length of the amino acid alkyl chain. At the same time, for the cyclic and chain amino acid anions with similar size ([Asp]²⁻ and [Pro]⁻), the movement of CO₂ in the chain-type anions is greater than the cyclic-type. We hypothesis that the diffusion of CO₂ in the AAIL system is related to the anion structure (the interaction of CO₂ and the anion of the AAILs will be discussed in detail below). Besides, no matter what the AAILs is, the self-diffusion coefficient of all ions increases as temperature increases (Table S1).

Table 2. Self-diffusion coefficients (unit: 10⁻¹² m²/s) of the cation/anion and CO₂ in all CO₂-AAILs systems.

D	[P4444] ⁺						[P66614] ⁺					
	[Gly] ⁻	[Pro] ⁻	[Lys] ⁻	[Asp] ²⁻	[Suc] ⁻	[Im] ⁻	[Gly] ⁻	[Pro] ⁻	[Lys] ⁻	[Asp] ²⁻	[Suc] ⁻	[Im] ⁻
Anion	1.47	0.84	1.68	2.44	1.58	0.65	1.96	1.73	1.02	3.51	5.17	1.23
Cation	0.97	0.75	1.26	2.47	1.61	0.83	1.15	0.71	0.63	2.51	1.66	0.62
CO ₂	56.21	51.43	39.66	72.73	53.67	51.29	94.35	66.41	61.18	101.36	45.46	93.53

3.2.2 Residence Time

Over time, the absorption and structure of CO₂ in AAILs fluctuates constantly. The residence time between CO₂ and anion or cation was further calculated to consider the dynamical property of CO₂-AAILs. Herein, the residence time correlation functions (R(t)) is calculated by

$$R(t) = \frac{1}{N_r} \sum_{n=1}^{N_r} \sum_j \langle \theta(r_i, 0) \theta(r_i, t) \rangle$$

Where $\theta(r, t)$ the heavyside step function, when the CO₂ molecule i stays in the first coordination shell, its value is 1; when it leaves the first solvation shell, its value is 0. N_r is the coordination number of the CO₂ molecules in the first solvation shell and t is the time? The $R(t)$ for the cation and anion in different AAILs are both shown in Figure 2(b). As expected, there is a strong positive correlation with the anion size, the residence time decreases in the order [Lys]⁻, [Asp]²⁻, [Suc]⁻, [Im]⁻, [Pro]⁻, [Gly]⁻ for anions around the CO₂. The shortest residence time for amine acid anion is [Gly]⁻, which should originate from its strong interaction energy. (We will discuss this in detail later). To the best of our knowledge, the fast diffusion of CO₂ is also meaningful for the capture of CO₂, which can promote the absorption and desorption process of CO₂ in ILs and reduce the related energy consumption. As shown in Table 2 and Figure 2(b), the residence time has a negative correlation with CO₂ diffusion (the order of the diffusion coefficient is opposite to the residence time for chain-type anion). At the same time, the chain length and the number of carboxyl groups also affect the absorption and diffusion of CO₂, that is, the shorter the chain and the larger number of -COOH group, the higher the absorption capacity. At the same time, in order to clarify the influence of temperature on the dynamic characteristics of CO₂ in AAILs, Figure S1 shows the change of CO₂ residence time at three different temperatures. Obviously, due to the high kinetic energy of CO₂, as the temperature increases, the residence time gradually decreases.

3.3 Mechanism of AAILs absorbing CO₂

3.3.1 Microstructural analysis of CO₂-AAILs

Exploring the structure between CO₂ molecules and AAIL at the micro-level is very important to understand the effect of CO₂ absorption. In general, the radial distribution function (RDF) and the spatial distribution function (SDF) from MD simulation are provide molecular insight into exploring the relative position of the cation/anion and CO₂ in the microstructure of CO₂-AAILs system. The center of mass of the RDF for anion-CO₂ and cation-CO₂ were shown in Figure 3(a) and (b) to investigate the effect of different types of AAILs on the distributions of the CO₂ molecular. Obviously, regardless of the AAILs and temperatures (Figure S2) the primary peak in the $g(r)$ plots of the CO₂-anion is sharper and more intense; however, a weaker and broader peak exists between the cation and CO₂ molecules. At the same time, comparing Figure 3(a) and (b), the average position of the primary peak for CO₂-anion and CO₂-cation were calculated: 0.57 nm for the [P₄₄₄₄]⁺ cation and 0.46 nm for anions. This result indicated that due to the steric hindrance caused by the phosphorus atoms on the cations (both [P₄₄₄₄]⁺ and [P₆₆₆₁₄]⁺) with a large number of positive charges and with longer alkyl chains, the interaction between the CO₂ molecules and the cations is weak. At the same time, the anion of ILs dominates the interaction between CO₂ and AAILs, which is consistent with the investigations of the simulation study by Zhang *et al.*¹² and the experimental

study by Sergei *et al.*³⁷ To further reveal the influence of different anion structures on the effect of CO₂ absorption, the interaction between CO₂ and anion (Figure 3(b)) were carefully compared. Clearly, the position of the primary peak of the CO₂-anion in the CO₂-[P₄₄₄₄] [X] follow the order: [Lys]⁺> [Asp]²⁻> [Suc]⁻>[Pro]⁻>[Im]⁻> [Gly]⁻. It reflects the fact that it is more effective to absorb CO₂ by chain-type AAILs, rather than cyclic-type of AAILs. Meanwhile, by comparing the different chain lengths of the chain-type structure of amino anion ([Gly]⁻, [Asp]²⁻, and [Lys]⁻) for AAILs, we found that the distance between anions and CO₂ decreases as the chain length increases. The results indicated that the alkyl chain in amino acid anion will affect the interacting distance between anion and CO₂, *viz.*, the alkyl chain hinder the free motions of CO₂ molecule in the CO₂-AAILs systems. It is the main reason why the diffusion rates of the CO₂ are slow in the longer alkyl chain amino acid anions systems (Table 2). In addition, obviously, regardless of the AAILs and temperatures (Figure S2), the primary peak in the g(r) plots of the CO₂-anion always appear at the position of around 0.46-0.49 nm, indicating that the CO₂ always have strong coordination with the AAILs and the structural stability is affected less by the temperature. To visually describe the spatial distribution of CO₂ and AAILs, the spatial distribution function (SDF) for CO₂ molecule around different types of anion for AAILs are further analyzed. As shown in Figure 3(c), for the cyclic-type anion (such as [Suc]⁻), the CO₂ molecule prefers to locate above and below the ring plane. However, the CO₂ exhibits a strong affinity toward the most negatively charged oxygen atom on the -COOH group of the anions for chain-type anion, which corresponds well with the RDF in Figure 4(b). Furthermore, since the coordination number N(r), which represents the average number of CO₂ molecules within a sphere of radius *r* around the mass of the center of anion/cation for AAILs. It could be used as a quantitative parameter to measure the absorption capacity of AAILs,³⁸ as shown in Figure 3(d) in which the coordination number of CO₂-cation and CO₂-anion were analyzed, respectively. It is found that the coordination number for CO₂ around [P₄₄₄₄]⁺ cation is higher than that around anions. The same conclusions were drawn by Li *et al.*³⁸ in their simulation study of the CO₂-metal based ILs. In addition, the coordination numbers (*N(r)*) of the CO₂-anion for all CO₂-[P₄₄₄₄][X] systems were calculated: *N*(CO₂-[Gly])=10.7, *N*(CO₂-[Im])=8.4, *N*(CO₂-[Pro])=6.3, *N*(CO₂-[Suc])=6.0, *N*(CO₂-[Aps])=5.6 and *N*(CO₂-[Lys])=4.0. Therefore, for the chain-type amino acid anion, the absorption capacity of the AAILs for CO₂ decreases as the increased chain length increases.

Figure 3. (a)-(b) Radial distribution function between CO₂ and the center of mass of cation and anion of [P₄₄₄₄] [X] at 300 K. (c) The spatial distribution function for CO₂ molecules (green) around [Asp]²⁻ and [Suc]⁻ anion. (d) The coordination number between CO₂ and anion or cation in different AAIL systems at 300 K.

3.3.2 Stable Adsorption Sites

Herein, in order to demonstrate the stable absorption sites in the process of CO₂ absorption by AAILs, the site to site RDF and DFT method (mentioned in Section 2.2) was used to analyze for anion-CO₂ in all systems. As Figure 4(b) shown, the site to site RDF of the carbon (C) atom from CO₂ molecular with the oxygen (O), nitrogen (N) and carbon (C) atoms from the anion of AAILs were investigated to shed light on the coordination mechanism of the CO₂ and AAILs. Take the CO₂-[P₄₄₄₄] [Gly] system as an example, where the interactions of the C(CO₂)-O([Gly]), C(CO₂)-C([Gly]), C(CO₂)-P([Gly]), C(CO₂)-N([Gly]) were demonstrated. Obviously, the strengths of these interactions follow the order: C(CO₂)-O([Gly]) > C(CO₂)-C([Gly]) > C(CO₂)-N([Gly]), implying that each CO₂ molecular preferentially coordinates with the O([Gly])

atoms in the carboxyl group, not the more electronegative N atom in amine group (-NH₂). This phenomenon proves the importance of the carboxyl group in AAIL anion for CO₂ absorption.

Further, in order to clarify the role of the different type of anion with amino (-NH₂) and carboxyl (-COOH) groups in AAILs in CO₂ absorption, the DFT calculations were performed on CO₂- anions to obtain the optimized structure and the lowest interaction energy. As shown in Figure 4(a), for chain-type anion (eg. [Gly]⁻), the most stable site of CO₂ and anion is near the -COOH group, the distances between -COOH group in [Gly]⁻ and CO₂ were calculated to be 2.81 Å and 2.58 Å for O(-COOH) ...C (CO₂). This indicated that the C atom in CO₂ molecule could equilibrate in the center of two O atoms in the carboxyl group, meanwhile, the O=C=O bend angle is 169.36° and the lowest interaction energy of -11.95Kcal/mol. For cyclic-type anion (such as [Pro]⁻), the stable site is at the center of -COOH and -NH₂ group, the distance between these two groups and CO₂ were calculated to be 2.56 Å for O...CO₂ and 2.83 Å for N...CO₂, the O=C=O angles in [Pro]-CO₂ amount to 168.46°. This phenomenon proves that the amino acid anion for improving the absorption of CO₂ by ILs through multiple site cooperation. In addition, the interaction energy of CO₂-anion of [Asp]²⁻, [Im]⁻, [Gly]⁻, [Lys]⁻, [Suc]⁻ and [Pro]⁻ were -18.89Kcal/mol, -18.31Kcal/mol, -11.95Kcal/mol, -10.35Kcal/mol, -9.48Kcal/mol and -9.27Kcal/mol, respectively. This indicated that the chain-type structure of amino acid anion is more effective in absorbing CO₂ than cyclic-type anion. At the same time, the Infrared Radiation (IR) spectrum of different CO₂-anion pairs were further calculated by DFT calculations and shown in Figure 4(c). The obvious blue shift was exhibited of the vibrational mode between C-O atom, where the frequency $\nu(\text{C-O})$ of [Asp]²⁻, [Pro]⁻, [Gly]⁻, [Suc]⁻ and [Lys]⁻ are 546.7, 571.4, 572.8, 618.8, and 624.9 cm⁻¹, respectively. This phenomenon due to the electron transfer from the O atom to the CO₂ molecule. Meanwhile, the transferred electron could further enhance the C=O bond, which agrees well with the vibration mode shown in Figure 4(c).

Figure 4. (a) The relaxed structure of CO₂-anion in different AAILs from the DFT calculations. (b) The site-site RDF between C/N/O atoms in -COOH, -NH₂ group of anion and C atom in CO₂ for [P₄₄₄₄] [Gly]-CO₂ system at 300K. (c) The IR spectrum for different CO₂-anion pairs calculated from the DFT calculations.

3.3.3 Energetic Interactions between CO₂ and Ionic Liquids.

To help understand the mechanism of cation and anion for CO₂ absorption in different AAILs, the van der Waals (vdW), electrostatic (elec) and total energy between the CO₂ molecular and AAILs were computed from 20NVT MD at varying temperatures (Table 3 and Table S2). It can be seen that the electrostatic energy is higher than the van der Waals energy for anion-CO₂ whereas an inverse trend is observed for cation-CO₂, which consistent with our previous research.¹² Meanwhile, the lower electrostatic

energy between cation and CO₂ is attributed to the more localized charge on the [P₄₄₄₄]⁺ cation. For CO₂-[P₄₄₄₄][Gly] and CO₂-[P₄₄₄₄][Im] the vdW interaction between CO₂ and the cation is about 10 times of the electrostatic energy. For the [Suc] anion that is like [Im] and is also symmetrical structure, the vdW energy of CO₂-[P₄₄₄₄] is significantly reduced, and the vdW energy is 5 times of the electrostatic energy. While, for the asymmetrical ring-type structure [Pro]⁻, the vdW energy of CO₂-cation is reduced to 4 times the electrostatic energy. These results indicate that the interaction between CO₂ and the same cation also depends on the anion. The size and shape of the anion have a significant influence on the mechanism for CO₂ absorption in ILs. For CO₂-anion, the small size and asymmetry of [Gly] results in more "free" volume to accommodate CO₂, which leads to increased electrostatic interaction between CO₂ and anions. As the chain length increases, the electrostatic energy between anion and CO₂ gradually weakens. Furthermore, for the common cation ([P₄₄₄₄]⁺) the total energy of CO₂-AAILs follows the order: [Gly]⁻ > [Im]⁻ > [Asp]²⁻ > [Lys]⁻ > [Suc]⁻ > [Pro]⁻. Interestingly, for the chain-type anion ([Gly]⁻, [Asp]²⁻ and [Lys]⁻) the order were agree well with the coordination number (Section 3.3.1), indicating the lower interaction energy may lead to the more coordinate of CO₂ around the anion. In a word, the ILs with high CO₂ adsorption capacity need to possess both the strong van der Waals energy for the CO₂-cations and the electrostatic energy on the CO₂-anions. The same conclusion was also reported by Zhang *et al.*³⁹

Table 3. Interaction Energy for all the AAILs-CO₂ systems

AAIL	Anion-CO ₂ (Kcal/mol)		Cation-CO ₂ (Kcal/mol)		Interatction Energy of AAIL-CO ₂ (Kcal/mol)
	E _{ele}	E _{vdW}	E _{ele}	E _{vdW}	
[P ₄₄₄₄][Gly]	-3.68±0.10	-2.53±0.02	-1.01±0.05	-10.29±0.04	-17.51
[P ₄₄₄₄][Im]	-2.19±0.08	-2.75±0.03	-1.08±0.04	-10.38±0.06	-16.4
[P ₄₄₄₄][Pro]	-0.14±0.04	-1.71±0.03	-1.15±0.01	-4.59±0.08	-7.59
[P ₄₄₄₄][Lys]	--1.35±0.07	-3.11±0.06	-0.93±0.03	-6.73±0.11	-9.42
[P ₄₄₄₄][Suc]	-0.11±0.04	-1.94±0.04	-1.25±0.01	-5.05±0.09	-8.35
[P ₄₄₄₄][Asp]	-0.41±0.11	-1.15±0.03	-1.34±0.03	-6.65±0.12	-9.55

3.3.4 Effect on Microscopic Structure of Ionic Liquid by CO₂.

To further reveal the influence of the microstructure of AAILs on CO₂ absorption, especially the influence of anions with -COOH and -NH₂ groups on AAILs, three different RDFs for anion-anion, cation-cation and cation-anion were calculated. As shown in Figure 5 and Figure S3, the order of the position of the primary peak for RDF (anion-anion) is [Im]⁻ < [Gly]⁻ < [Suc]⁻ < [Pro]⁻ < [Lys]⁻ < [Asp]²⁻, indicating the carboxyl group could enlarge the value of the distance of the first peak. At the same time, the position of the primary peak is positively correlated with the number of carboxyl groups, that is, the more carboxyl groups, the farther the position of the primary peak is. For RDF (cation-cation), most of the first peak positions are around 0.82nm, however for [Lys]⁻ anion, the position of the first peak in the g(r) plot of the cation-cation shifts backward from 0.81nm to 1.1nm (Figure S3). This result indicates that the longer-chain amino acid anion has a greater influence on the cation microstructure. Interestingly, the order of position of the first peak for cation-anion is consistent with that of the anion-anion, indicates that the structure of anions in AAILs can be used as an effective variable to adjust the microstructure of ILs. Therefore, amino acid anions, especially the anions of two carboxyl groups, have the greatest impact on the structure of AAILs, which can effectively promote the absorption of carbon dioxide molecules. Besides, in order to quantitatively describe the changes in the microstructure of AAILs caused by CO₂, the coordination number also calculated for anion-anion, cation-cation and cation-anion pairs and shown in Figure 5(b). It can be seen that the order of the coordination number for cation around anions is [Lys]⁻ < [Pro]⁻ < [Suc]⁻ < [Asp]²⁻ < [Im]⁻ < [Gly]⁻, which is consistent with the coordination number for cation around cation. The observations further demonstrated the [Gly]⁻ anion has the best absorption capacity, meanwhile, due to the larger size of [Lys]⁻ and [Pro]⁻, the coordination number is lower. Therefore, we have reason to believe that the size of anion in AAILs is a key factor affecting CO₂ absorption, and this phenomenon is crucial to the design of AAILs on molecular level.

Figure 5. (a) The center of mass RDF for anion-anion cation-cation and cation-anion pair. (b) The position of the first peak for three types of RDFs; (c) The coordination number of anion-anion, cation-cation, and cation-anion pairs in [P₄₄₄₄] [X] ([X]=[Asp]²⁻, [Gly]⁻, [Im]⁻, [Lys]⁻, [Pro]⁻, and [Suc]⁻) at 300 K.

4. Conclusions

Amino acid ionic liquids used as absorbents in gas absorption could improve the efficiency and greenness of the absorption process, thereby increasing the ability to resist climate warming. Fundamental molecular insights are useful for understanding the advantages of AAILs. In this work, atomic MD

1 simulations and first-principles calculations are used to study the capabilities and effects of six different
2 ionic liquids with amino and carboxyl groups in absorbing CO₂.

3 We firstly calculated the density and dynamics properties of all the CO₂-AAILs systems. Simulation
4 results revealed that the larger size of cation have lower density and larger self-diffusion coefficient. At the
5 same time, the density and kinetic characteristics of the system increase with the increase of the number of
6 anionic carboxyl groups. For anions of similar size, chain-type anions perform better in dynamic
7 characteristics than cyclic-type anions. Later, we evaluated the radial distribution function (g(r), spatial
8 distribution function (sdf), coordination number, intermolecular interaction energy (vdW and electrostatic
9 energy)) to clarify the effect of different amino acid ionic liquids on the absorption of CO₂ Influence and
10 internal mechanism. At the same time, DFT analysis and site-to-site RDF calculations revealed the stable
11 absorption sites of AAILs in the absorption of CO₂. The result indicated that due to the steric hindrance
12 caused by the phosphorus atoms with a large number of positive charges and with longer alkyl chains on
13 the cations, the interaction between the CO₂ molecules and the cations in AAILs is weak. Meanwhile, we
14 realized that the absorption of CO₂ in AAILs is an anion-driven process. The coordination number and
15 interaction energy jointly suggest that the absorbing capacity of AAILs increasing in the order [Asp]²⁻,
16 [Suc]⁻, [Lys]⁻, [Pro]⁻, [Im]⁻, [Gly]⁻. At the same time, it is more effective to absorb CO₂ through chain AAIL
17 instead of cyclic AAIL. And the alkyl chain in the chain anion will affect the absorption between the anion
18 and CO₂, that is, the longer the alkyl chain will hinder the free movement of CO₂ molecules in the CO₂-
19 AAILs system, and affect the absorption efficiency. The calculation result of DFT proves that absorption
20 of CO₂ is a multi-site cooperative way by AAILs. For chain anions, the most stable sites for CO₂ and anions
21 are located at the center of the two O atoms in the -COOH group, and for cyclic anions, the stable site is
22 located at the center of the -COOH and -NH₂ groups. Therefore, in the molecular design strategy of AAILs,
23 short chain-type anions or anions with a large number of -COOH groups should be prioritized to enhance
24 the performance of IL in the CO₂ absorption process.
