## 2 Introduction

---

The work of Subtask 2P is split into 4 topic:

- Material development
- Developing measurement procedures
- Filling the PCM Database
- Developing a Wiki for terms used in the context of PCMs

As the material development is done at different institution the objective of the work was to collect the materials which are under research and development to get an overview on the most relevant properties of these materials and application which are addressed.

In the frame of this subtask investigations on results obtained at different institutions using various measurement methods for different material properties have been conducted. Procedures have been developed, for thermal conductivity and the determination of viscosity.

New material properties have been feed into the database which was developed during previous tasks and annexes.

And finally a wiki for the terms uses in the context of PCMs have been developed based on a content management web based tool.

---

## 3 Material development; List of novel developed PCMs as well as blends and mixtures (D2P1)

---

The objective of this work was to collect the PCMs and applications focused on within the participants of the SHC Task 58 and ECES Annex 33 (TA5833). Another target is to determine the challenges of the development process. For the collection of this data a questionnaire was prepared which was sent to the TA5833 mailing list. Nine different institutions reported about the development or investigation of 20 different materials and the supposed applications (Annex from page 16).

### PCMs

- Organic (alkanes, fatty acids, sugar alcohols and others)
- Inorganic (salt hydrates, salt)
- Eutectic mixtures (organic, inorganic)

### Applications

- Cold storages, precooling of refrigerants
- Passive cooling for buildings and industrial processes
- Heat pump applications
- Mobile heat storage
- Waste heat / process heat / steam generation
- Thermal protection of electronics / battery cooling
- Solar heating / long term storage

The main work is done on organic PCMs and on mixtures of either organic or inorganic materials. Figure 1 is indicating the materials which are under research. The majority of materials are developed for storage temperature below 100 °C. A few materials are under research in the temperature range between 100 und 150 °C. Above 150 °C many institutions doing research on d-Mannitol, which is only once rated as stable as well as a mixture of d-Mannitol and Ducitol. Another material which is under research on this temperature level is hydroquinone, which is also rated as not stable.

Supercooling of almost all materials is below 10 K except d-Mannitol, pinacone hexahydrate, and sodium acetate trihydrate. The last one was optimized to be used as supercooled storage material.

Almost all contributors tested the stability of materials by thermal cycling except one who kept the temperature above the melting point. The number of cycle has been very different and reaches from 5 up to 5000 cycles. There is no clear indication for stability e.g. based on a limit for the decrease of enthalpy or change in phase transition temperature.

Figure 1: Overview on materials collected with their phase change enthalpy and melting temperature, red indicates the unstable materials

Figure 2: Supercooling behaviour of the materials

Figure 3: Stability of materials, number of cycles tested

## 4 Characterization of PCMs; Extended list of material properties for the characterization of novel PCM (D2P2)

### 4.1 Thermal conductivity

An intercomparative test of thermal diffusivity was carried out under the guidance of ZAE Bayern. The scope of the test was to develop a guideline for determination of thermal diffusivity and conductivity of PCM by means of flash technique in order to ensure reliable measurement data.

The investigated sample material was RT70HC provided by Rubitherm and was from the same batch used for the DSC intercomparison of IEA SHC Task 42 ECES Annex 29. The melting range of the PCM is around 70 °C.

In the first comparison in Task 42 Annex 29 different measurement methods were used and no procedures for the measurement and specimen preparation were defined. The results showed high deviations in the measurement results between the different laboratories (standard deviation of about  $\pm 30\%$ ). Therefore, it was decided to continue the work in Task 58 Annex 33.

To reduce the number of different measurement methods, it was decided to focus on the flash method, since it is the method available in most laboratories.

In order to avoid deviations caused by the sample preparation, the measured specimens were all prepared by the pilot laboratory. Since the cooling rate of the material has an influence on the crystal structure of the material and again the thermal conductivity, the specimens were prepared with two significantly different cooling rates (slow: 2 K/h; fast: LN<sub>2</sub>).

In the first measurement round the thermal diffusivity of the solid PCM RT70HC was measured at 40 °C and 50 °C by five different laboratories with the flash technique. The results showed a lower standard deviation in the measurement results for the different cooling rates and a significant difference in the thermal diffusivity values between the different cooling rates of about 23 %.

In the second measurement round the pulse energy was varied systematically. With rising pulse energy a trend towards lower thermal diffusivity can be observed for all measurements. The values at 0% pulse energy are calculated by linear extrapolation of the measured values. By this procedure the standard deviation of the results are reduced again.

In a third measurement round the specimens were prepared by the participating laboratories in order to test the influence of sample preparation. Compared to the previous measurement rounds, the standard deviation of the results was increased. In Table 1 the statistical results of the different measurement rounds are compared and in Figure 4 the results of the third measurement round are compared to the results of the previous Task/Annex.

**Table 1: Relative standard deviations of the measurement results in the different measurement rounds for specimens with different cooling rates.**

**Figure 4: Comparison of thermal diffusivity measurement results from Task 42 Annex 29 and Task 58 Annex 33.**

## 4.2 Viscosity

This work was led by the University of Zaragoza. A comparison of viscosity measurement devices was conducted for which Uni. Zaragoza, Uni. Bayreuth, and Fraunhofer ISE contributed. A publication on this was done in 2018<sup>1</sup>. Figure 5 depicts two results from this publication, which show the comparison of a measurement using a standard oil and of a paraffin.

**Figure 5: Comparison of different measurement devices for viscosity, left: comparison of a standard oil, right: comparative measurement of a paraffin**

At Marche 7th and 8th 2018 a workshop on viscosity measurement of paraffin and salt nitrates was organised by the University of Zaragoza and hosted by Fraunhofer ISE in Freiburg. For the workshop Rheometers from TA-Instruments, Anton Paar and Thermo-Scientific were available in the lab. Previous to the measurement in the lab presentation were given by:

- Monica Delgado (Uni. Zaragoza) on the measurement procedure for PCMs
- Helena Navarro (Uni. Birmingham) on the measurement of high temperature PCMs
- Stephan Höhle (Uni. Bayreuth) on the IMETER measurement principle
- Mr. Schwab, TA-Instruments, introduction into DHR 2 Rheometer

Figure 6 shows some impressions from the workshop and Figure 7 shows the viscosity of RT70HC in dependency of temperature.

Figure 7: Example: result on the measurement of RT70HC, measuring from liquid to the phase transition, oscillatory method

## 4.3 cp-Measurement via DSC

### 4.3.1 Comparison of measurements

A comparison of specific heat capacity measurement via DSC was conducted. Five institutions contributed to this comparison. The measurements were done using different heating rates to determine the influence of low heating rates on the results. The target was to determine the resolution errors that are made using different DSCs and to check whether slow measurement is possible as the procedure to measure the enthalpy is based on slow heating rates. The results show, that for some devices slow heating rates lead to larger deviations (Figure 8), which is also observed in the comparison of the different results (Figure 9). The result shows that for a common measurement procedure to determine  $c_p$  of PCMs it is not possible to use slow heating rates. Therefore the measurement according to ASTM 1269 is suggested.

### 4.3.2 Method suggestion based on ASTM 1269

Short abstract from the ASTM1269 (not complete):

Reference Material—Synthetic sapphire.

1. Purge the DSC apparatus with dry nitrogen (or other inert gas) at a flow rate of 10 to 50 mL per min throughout the experiment.
2. Weigh a clean, empty specimen holder plus lid to a precision of 60.01 mg. Record as the tare weight.
3. Position the empty specimen holder plus lid and a reference specimen holder plus lid (weight-matched, if possible) in the DSC apparatus. NOTE 7—The same reference specimen holder + lid should be used for the sapphire standard run and for the test specimen run.
4. Heat or cool the DSC test chamber to the initial temperature for the experiment at 20 °C/min.
5. Hold the DSC test chamber isothermally at the initial temperature for at least 4 min to establish equilibrium. Record this thermal curve (refer to 12.4).
6. Heat the test specimen from the initial to final temperature at a rate of 20 °C/min. Continue to record the thermal curve. NOTE 8—The precision of this test method is enhanced by this high heating rate. Other heating rates may be used but shall be reported.
7. Record a steady-state isothermal baseline at the upper temperature limit. Refer to 12.4.
  - 7.1. Terminate the thermal curve after this period.
  - 7.2. Cool the DSC test chamber to ambient temperature.
8. Place the sapphire standard into the same specimen holder plus lid used in 13.1.2.
9. Weigh sapphire standard and specimen holder plus lid to a precision of 0.01 mg and record the weight.

Following the additional definitions (12., 13., 14., and 15.) for conditioning , procedure, calculation and report.

## 4.4 Density measurement

A comparison of density measurement was undertaken. The contributors used different technologies for the measurement (oscillating U-tube, Archimedes principle, helium pycnometer). Results are shown in Figure 12. The results reveal large deviations between measurement principals and different institutions. During the TA5833 it was decided not to proceed with this task.

Figure 13: Comparison of density measurement done at different institutions

# 5 Database; Measured material data for the maintenance and expansion of the PCM Database (D2P3)

## 5.1.1 Database

The database has a private and a public section. Data of 56 measurements are available in the private section from which 16 datasets are publicly available. The last material uploaded was in October 2019. Figure 12 shows on the overview table of public available materials. Figure 13 illustrates one example for details available for a PCM.

## 6 Wiki for PCM

A Wiki was developed to document the nomenclature which is used in the field of PCMs. The Wiki is open, so that everybody can add new terms and definitions or to change existing ones. Figure 16 shows a screenshot.

- Offset Temperature
- Onset Temperature
- Baseline
- Melting Temperature
- Nucleation or Crystallization Temperature
- Peak Temperature
- Enthalpy
- Zero-line
- Subcooling
- Supercooling
- T-History
- Nucleation
- DSC
- Specific heat determination (DSC)

### Wiki PCM

#### How to use and edit

To put a new entry to the Wiki go to the Wiki-PCM page and choose "Add new" -> "Page", give the title and go to "Body Text" to write the description. Therefore insert a table with 2 cols and 1 row. Please write text using format "Heading cell" into the left col and put images into the right col. You can also use subheadings to include sub headings in your text.

Please insert images here (tree icon above) (graphs, pictures fotos) use png or jpg format. Best image width is 285 dots. Therefore upload images to the image-folder in Wiki-PCM (see description there).

You can publish the new entry by choosing "publish" after you have saved the text (bottom below).

#### Offset Temperature

The extrapolated offset-temperature (according to DIN EN ISO 11357-1:2010-03) is the designed intersection point of the extrapolated baseline and the inflectional tangent at the end of the melting or crystallization peak (see image onset temperature). The baseline and the inflectional tangent are determined from the temperature-dependent heat flow signal.

#### Onset Temperature

The extrapolated onset-temperature (according to DIN EN ISO 11357-4:2010-03) is the designed intersection point of the extrapolated baseline and the inflectional tangent at the beginning of the melting or crystallization peak. The baseline and the inflectional tangent are determined from the temperature-dependent heat flow signal. In the case of pure and homogeneous materials, the onset-temperature can be indicated as melting temperature. In contrast to peak-temperature, the onset-temperature is less dependent on heating rate and sample mass. Furthermore onset-temperatures are usually used for temperature calibration of a DSC.

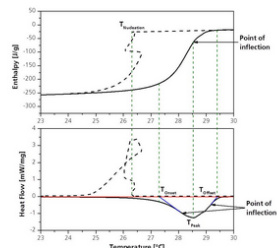

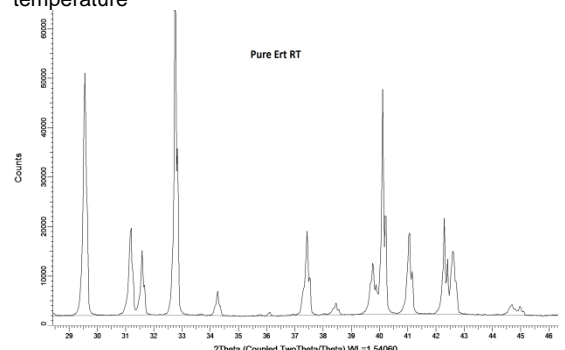

Figure 16: Screen shot of the Wiki for PCM ([www.thermalmaterials.org/wiki-pcm](http://www.thermalmaterials.org/wiki-pcm), 30/01/2020)

Thermally activated change in Erythritol [Gunasekara et al., 2016]:

#### Target Applications (up to 4 most relevant)

1. district heating
2. mobile heat storage
- 3.
- 4.

#### Comments

The main reason for the low melting enthalpy is possibly the thermally activated change (browning and thickening of material at the end of the T-history cycles, conducted within air). However, the literature data for the melting enthalpy of erythritol are also very disparate, within a very wide range: 281–370 kJ/kg, most often presented without specifying the number of cycles these values represent, and if specified, mostly representing only the first melting.

The reuse of this given photograph of the browned erythritol may require permission from the publisher of Gunasekara et al., 2016 (Elsevier).

<b>Material Data/Information</b>		Date: 21.12.2017	
<b>Material Designation</b> Xylitol (99% purity), thermo-physical characterizations using the T-History, TPS and XRD methods			
PCM (single component (U)/ composite (Cm) or, a blend: binary (B)/ ternary (T)..., eutectic (E)/ solid solution (Ss)/ compound (C))		Composite material(s)	
1. xylitol (U) 2. 3.		1. --- 2. 3.	
<b>Data for the component/ composite/ blend</b>			
Melting Temperature [°C] 90.6–97.7		Minimum Temperature [°C] 0 (min. of the measurement range)	
Storage Capacity [kJ/kg] 164±46		Maximum Temperature [°C] 138 (max. of the measurement range)	
Density [kg/l] Unevaluated		Cycle Stability (how many thermal cycles tested, if possible reduction in kJ/kg·h) ~5 cycles, and the given results exclude the very first melting. This given melting enthalpy is for the 2 <sup>nd</sup> melting, because, afterwards the melting enthalpy was extremely subtle, due to heavy influence of glass transition. This enthalpy seems at least 19-25 % lower than the literature values, possibly due to the cycled behavior analyzed here.	
Supercooling [K] Very large (as it becomes glassy)		Material compatibility Not yet tested systematically. Nevertheless, it appears to be compatible with metals, but cracks glass (especially at higher temperatures or during solidification respectively).	
Technology readiness levels (TRL) Unevaluated		Additional Parameter Thermal conductivity: 0.41-0.43 W/m K (liquid at 110 °C), and 0.37 W/m K (solid at 20 °C)	
If possible, please insert DSC-curve or other characteristic graph		Please insert an image/photo Xylitol X-Ray Diffraction (XRD) characteristics at room temperature	
		Thermally activated change in xylitol (browned thickened material) [Gunasekara et al., 2016]:	

Glassy nature of xylitol (the spatula is stuck within the extremely thick glassy liquid) [Gunasekara et al., 2016]:

#### Target Applications (up to 4 most relevant)

1. district heating
2. mobile heat storage
- 3.
- 4.

#### Comments

The main reasons for the low melting enthalpy are possibly the heavy influence of glass transition as well as thermally activated change (browning and thickening of material at the end of the T-history cycles, conducted within air). Another reason is that xylitol, before its stable melting, indicated a minor change at a lower temperature (see figures at left-side). The literature data for the melting enthalpy of xylitol are also disparate, within a wide range: 219-280 kJ/kg, most often presented without specifying the number of cycles these values represent, and if specified, mostly representing only the first melting.

The reuse of this given photographs of the browned xylitol and glassy xylitol may require permission from the publisher of Gunasekara et al., 2016 (Elsevier).

<b>Material Data/Information</b>		Date: 05.12.2017	
<b>Material Designation</b> <i>n</i> -tridecane (99%+ pure), thermal characterizations using T-History method			
PCM (single component (U)/ composite (Cm) or, a blend: binary (B)/ ternary (T)..., eutectic (E)/ solid solution (Ss)/ compound (C))		Composite material(s)	
1. <i>n</i> -tridecane CH <sub>3</sub> (CH <sub>2</sub> ) <sub>11</sub> CH <sub>3</sub> (U)		1. ---	
2.		2.	
3.		3.	
<b>Data for the component/ composite/ blend</b>			
Melting Temperature [°C] -6.7 to -4.5 (average over 2 <sup>nd</sup> to 4 <sup>th</sup> melting cycles)		Minimum Temperature [°C] -28 (min. of the measurement range)	
Storage Capacity [kJ/kg] 182±18 (average over 2 <sup>nd</sup> to 4 <sup>th</sup> melting cycles)		Maximum Temperature [°C] 8 (max. of the measurement range)	
Density [kg/l] Unevaluated		Cycle Stability (how many thermal cycles tested, if possible reduction in kJ/kg·h) 5 cycles, while the given results exclude the very first melting. The results agree well with the literature values.	
Supercooling [K] Negligible		Material compatibility Not yet tested systematically. Nevertheless, it appears to be compatible with metals and glass but incompatible with plastics.	
Technology readiness levels (TRL) Unevaluated		Additional Parameter Also undergoes a polymorphic phase change, between -19.4 °C and -18.2 °C (in heating) and -19.5 °C and -20.3 °C (in cooling) with the respective enthalpy changes 66 ± 7 kJ/kg and 46 ± 5 kJ/kg.	
If possible, please insert DSC-curve or other characteristic graph		Please insert an image/photo	

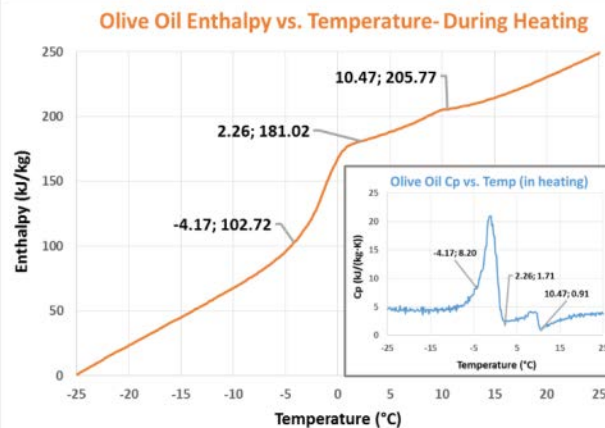

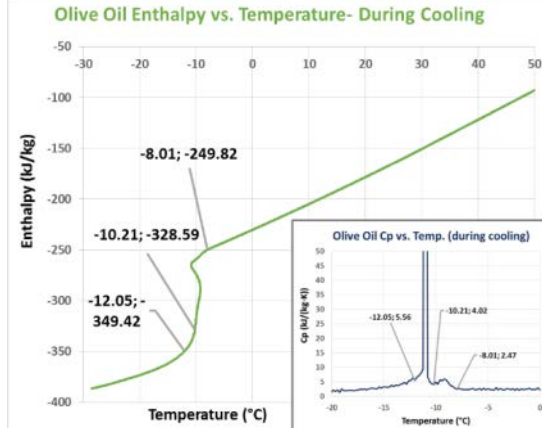

**Target Applications (up to 4 most relevant)**

1. pre-cooling of refrigerants
2. cold storage below 0 °C
3. solid-solid PCM applications for cooling (considering the polymorphic phase)
- 4.

**Comments**

The results shown are for the 3<sup>rd</sup> melting (and freezing) cycle (in the T-history evaluation). Nonetheless, for all the evaluated cycles the sample displayed very consistent behaviors during both melting and freezing. This material (*n*-tridecane) also undergoes a polymorphic phase change (detailed under 'Additional Parameters').

<b>Data for the component/ composite/ blend</b>			
Melting Temperature [°C] -4.5 to 10.3 (average over 2 <sup>nd</sup> to 4 <sup>th</sup> melting cycles, of 2 identical samples)		Minimum Temperature [°C] -30 (min. of the measurement range)	
Storage Capacity [kJ/kg] 104±10 (average over 2 <sup>nd</sup> to 4 <sup>th</sup> melting cycles, of 2 identical samples)		Maximum Temperature [°C] 80 (max. of the measurement range)	
Density [kg/l] Unevaluated		Cycle Stability (how many thermal cycles tested, if possible reduction in kJ/kg·h) 4 cycles, while the given results exclude the very first melting. The results agree well with the available literature values.	
Supercooling [K] Minor (~2 K)		Material compatibility Not yet tested systematically. Nevertheless, it appears to be compatible generally with metals, glass and plastics.	
Technology readiness levels (TRL) Unevaluated		Additional Parameter Hysteresis is rather considerable (3.5 -22 °C), primarily due to its wide melting temperature range.	
If possible, please insert DSC-curve or other characteristic graph		Please insert an image/photo	
			
		Frozen Olive oil samples (from a simple freezing pre-test):	

	
<b>Target Applications (up to 4 most relevant)</b> <ol style="list-style-type: none"> <li>1. pre-cooling (within -4.5 to 10.3 °C) in chilling applications</li> <li>2.</li> <li>3.</li> <li>4.</li> </ol>	
<b>Comments</b> <p>The results shown are for the 3<sup>rd</sup> melting (and freezing) cycle (in the T-history evaluation), for one of the 2 tested identical samples. For all the evaluated cycles the samples anyways displayed very consistent behaviors respectively during melting and freezing.</p> <p>The samples displayed a secondary phase change peak (which is a possible solid-solid phase change) consecutively before the melting <math>c_p</math> peak or, after the freezing <math>c_p</math> peak, respectively. This secondary peak was however smaller during cooling, as compared to that observed during heating.</p> <p>This secondary peak could be an indication of a near-eutectic composition in this multicomponent blend, or could be a polymorphic phase incurred due to the major triglyceride component in olive oil: triolein. The study indicates that: olive oil is not recommendable as a PCM as it is, however, compositional refinements could yield an attractive renewable PCM out of it.</p>

<b>Material Data/Information</b>	Date: 21.12.2017
<b>Material Designation</b> 25-30 mol% Erythritol in Xylitol, thermal characterizations using the T-History and TPS methods	
PCM (single component (U)/ composite (Cm) or, a blend: binary (B)/ ternary (T)... eutectic (E)/ solid solution (Ss)/ compound (C)) 1. Erythritol-Xylitol (BE), @ 25-30 mol% Erythritol 2. 3.	<b>Composite</b> material(s)  1. --- 2. 3.
<b>Data for the component/ composite/ blend (shown for 25 and 30 mol% Erythritol respectively)</b>	
Melting Temperature [°C] 80.6–101.6 and 80.0–91.1	Minimum Temperature [°C] 0 (min. of the measurement range)
Storage Capacity [kJ/kg] 59.5±17 and 45±13 (Total including melting as well as glassy and intermediate changes: 172±48 and 200±56)	Maximum Temperature [°C] 138 (max. of the measurement range)
Density [kg/l]	Cycle Stability (how many thermal cycles tested, if possible reduction in

Unevaluated	kJ/kg·h) ~5 cycles, and the given results exclude the very first melting. This given melting enthalpy is for the 2 <sup>nd</sup> melting, because, afterwards the melting enthalpy was extremely subtle, due to heavy influence of glass transition. This enthalpy seems at least 19-25 % lower than the literature values, possibly due to the cycled behavior analyzed here.
Supercooling [K] Very large (as it becomes glassy)	Material compatibility Not yet tested systematically. Nevertheless, it appears to be compatible with metals, but cracks glass (especially at higher temperatures or during solidification respectively).
Technology readiness levels (TRL) Unevaluated	Additional Parameter: <b>for 25 mol% erythritol</b> Thermal conductivity: 0.40 W/m K (liquid at 110 °C), and 0.39 W/m K (solid at 20 °C)

If possible, please insert DSC-curve or other characteristic graph

Please insert an image/photo

Erythritol-Xylitol Binary Phase Diagram [Gunasekara et al., 2018]

### Target Applications (up to 4 most relevant)

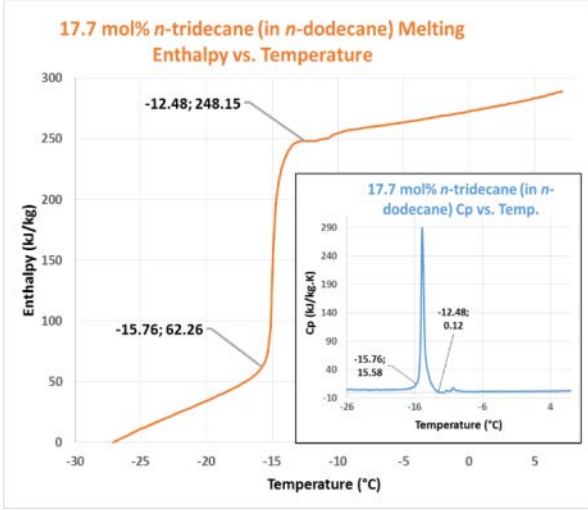

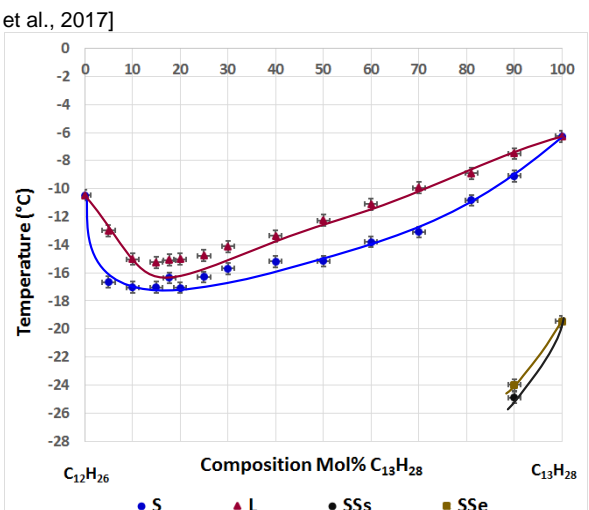

1. district heating
2. mobile heat storage
- 3.
- 4.

### Comments

The eutectic was also heavily affected by glass transition, thus resulting in a very low melting enthalpy. Furthermore, after the 2<sup>nd</sup> melting (which is what's shown here) the phase change was almost completely overcome by glass transition. This composition also underwent thermally activated change (browning and thickening of material at the end of the T-history cycles, conducted within air), which is another possible reason for lowered melting enthalpy. The literature data for the melting enthalpy of this eutectic blend is larger, however cannot be compared directly as those studies do not specify what cycle it represented.

The reuse of this given phase diagram may require permission from the publisher (Elsevier).

<b>Material Designation</b> <i>n</i> -dodecane- <i>n</i> -tridecane binary system (made from <i>n</i> -dodecane and <i>n</i> -tridecane (i.e., CH <sub>3</sub> (CH <sub>2</sub> ) <sub>11</sub> CH <sub>3</sub> and CH <sub>3</sub> (CH <sub>2</sub> ) <sub>11</sub> CH <sub>3</sub> ) of 99% and 99%+ purity), thermal characterizations using T-History method			
PCM (single component (U)/ composite (Cm) or, a blend: binary (B)/ ternary (T)..., eutectic (E)/ solid solution (Ss)/ compound (C))		Composite material(s)	
1. <i>n</i> -dodecane- <i>n</i> -tridecane (B, possibly congruent melting Ss), @ ~17.7 <i>n</i> -tridecane		1. ---	
2.		2.	
3.		3.	
<b>Data for the component/ composite/ blend</b>			
Melting Temperature [°C] -15.7 °C to -12.4 °C (average over 2 <sup>nd</sup> to 4 <sup>th</sup> melting cycles)		Minimum Temperature [°C] -28 (min. of the measurement range)	
Storage Capacity [kJ/kg] 185±19 (average over 2 <sup>nd</sup> to 4 <sup>th</sup> melting cycles)		Maximum Temperature [°C] 8 (max. of the measurement range)	
Density [kg/l] Unevaluated		Cycle Stability (how many thermal cycles tested, if possible reduction in kJ/kg-h) 5 cycles, while the given results exclude the very first melting. The results agree well with the literature values.	
Supercooling [K] Negligible		Material compatibility Not yet tested systematically. Nevertheless, it appears to be compatible with metals and glass but incompatible with plastics.	
Technology readiness levels (TRL) Unevaluated		Additional Parameter Hysteresis of this blend is also minor, of around 1-3 °C.	
If possible, please insert DSC-curve or other characteristic graph		Please insert an image/photo <i>n</i> -dodecane- <i>n</i> -tridecane Binary Phase Diagram [Gunasekara et al., 2017]	
			
<b>Target Applications (up to 4 most relevant)</b>			
1. pre-cooling of refrigerants			
2. cold storage below 0 °C			
3. solid-solid PCM applications for cooling (considering the polymorphic phase)			
4.			

**Comments**

The results shown are for the 3<sup>rd</sup> melting (and freezing) cycle (in the T-history evaluation). Nonetheless, for all the evaluated cycles the blend displayed very consistent behaviors during both melting and freezing. This system appears to form a congruent minimum melting solid solution at around 17.7 mol% *n*-tridecane composition. That therefore appears to be ideal as a PCM for freezing applications. However, as the phase diagram here was presented only based on thermal characterizations, physicochemical characterizations and cycling stability tests are necessary future steps to confirm its PCM-suitability.

The reuse of the phase diagram given may require permission from the publisher (Elsevier).

<b>Material Data/Information</b>		Date:	
<b>Material Designation</b> Eutectic mixture of Urea and Sodium Nitrate; phase diagram, thermal properties, crystallization behaviour, degradation, influence of water uptake			
PCM ( 1. Urea (71 % w/w) – NaNO <sub>3</sub> (29 % w/w) (eutectic mixture) 2. 3.		Composite material(s) 1. 2. 3.	
<b>Data for PCM or composite</b>			
Melting Temperature [°C] 85 °C (onset)		Minimum Temperature [°C] n.a.	
Storage Capacity [kJ/kg] 250 kJ/kg (60 to 95 °C) 172 kJ/kg (melting latent heat)		Maximum Temperature [°C] n.a.	
Density [kg/l] 1.48 solid / 1.42 liquid		Cycle Stability (how many thermal cycles tested, if possible reduction in kJ/kg·h) - DSC: Crucibles closed in air. 200 cycles. Reduction of 1.2 % of the original melting enthalpy. - Thermal stability of larger samples is currently under study. The results suggest that there is a significant reduction on the enthalpy in these larger samples, caused by a phase segregation phenomenon that is coupled to the thermal degradation of the sample (formation of ammonia due to the urea decomposition).	
Supercooling [K] DSC: around 20 °C Larger samples: 3-5 °C		Material compatibility Not checked. It may be corrosive in contact with some construction materials	
Technology readiness levels (TRL) 2/3		Additional Parameter none	
If possible, please insert DSC-curve or other characteristic graph that shows the temperature dependency		Please insert an image/photo	
			

<p>DSC results (heat flow vs. temperature) for the eutectic composition (71.25 % (w/w) urea)</p>	
<p><b>Target Applications (up to 4 most relevant)</b></p> <ol style="list-style-type: none"> <li>1. TES systems for Heating and DHW</li> <li>2. TES systems for low to medium temperature industrial residual heat</li> <li>3.</li> </ol>	
<p><b>Comments</b></p> <p>We are currently focused on the thermal degradation of the material. However, it is a complex procedure, because Urea undergoes thermal decomposition above its melting point. This effect is kinetic and depends on the time that the PCM stays above the melting temperature. Thus, accelerated thermal cycling studies are not useful to study it. Besides, the mixture tends to segregate when it crystallizes. This is dependent on the sample size and shape, but the effect cannot be decoupled from the thermal decomposition. Other variables such as the gas surrounding the mixture and the moisture content can have also a significant effect. All these factors together become the degradation study really complex.</p>

DSC thermograms obtained for the erythritol-xylitol system			
<b>Target Applications (up to 4 most relevant)</b>			
1. TES systems for Heating and DHW 2. TES systems for low to medium temperature industrial residual heat 3.			

**Comments**

So far, the studies have been focused on the thermal and crystallization behaviour. We have plans to investigate in the near future the thermal degradation of the mixture, as well as its potential application within a storage device that includes a crystallization triggering system.

<b>Material Data/Information</b>	Date:
<b>Material Designation</b>	
PCM Sodium Acetate Trihydrate (SAT)	Composite material(s). <b>Examples listed. SAT with different weight contents of water, thickening agents, polymer materials can be found in [1]</b> <ol style="list-style-type: none"> <li>SAT with 1% (wt %) CMC (Carboxymethyl Cellulose)</li> <li>SAT with 1% (wt %) water + 1% (wt %) EDTA (Disodium Ethylenediaminetetraacetic acid)</li> <li>SAT with 2% (wt %) EDTA</li> <li>SAT with 4% (wt %) water</li> <li>SAT with 2% (wt %) HD 200 (Polymer material)</li> <li>SAT with 0.5% (wt %) Xanthan Gum</li> </ol>
<b>Data for PCM or composite</b>	
Melting Temperature [°C] 58	Minimum Temperature [°C] -15 °C (crystallization of liquid SAT ) [3]
Storage Capacity [kJ/kg] [1] <ol style="list-style-type: none"> <li>211</li> <li>216</li> <li>215</li> <li>194</li> <li>216</li> <li>214</li> </ol>	Maximum Temperature [°C] ~100 °C for SAT composition except: 80 °C for compositions containing CMC (assuming atmospheric pressure conditions).
Density [kg/l] Depending on the state (liquid, solid, liquid supercooled), see reference [2] and diagram below  <p>Fig. 4. Density of solid and liquid SAT including SAT with extra water in supercooled state.</p>	Cycle Stability (how many thermal cycles tested, if possible reduction in kJ/kg-h)  Stable with above mentioned compositions. Cyclic stability was proven in large containers (heat storage prototypes) up to ~30 cycles. Long-term investigations are ongoing.
Supercooling [K] Down to -15 °C with 73 K degree of supercooling [3]	Material compatibility
Technology readiness levels (TRL) 6-7 [4]	Additional Parameter Thermal conductivity <ol style="list-style-type: none"> <li>SAT with 1% CMC 0.57-0.65 W/mK</li> <li>SAT with 0.5 % Xanthan Gum 0.5-0.65 W/mK</li> </ol> For more composites, reference [5]

If possible, please insert DSC-curve or other characteristic graph that shows the temperature dependency

Use heat loss method to measure the heat content [1]

Please insert an image/photo

Bulk sample below: SAT with 1% (wt. %) CMC

#### Target Applications (up to 4 most relevant)

1. Solar thermal heating system for DHW & SH
2. Domestic heating systems with heat pumps
3. Smart grid (increased demand flexibility of buildings)
4. Overall: stable supercooling for combined short – long term heat storage below 100 °C
