8 Abstract

9 Methyl vinyl glycolate (methyl 2-hydroxybut-3-enoate, MVG) has recently become obtainable from Sn 10 catalysed cascade reactions of mono- and disaccharides. The chemical structure of MVG present several 11 options for chemical transformations and has great potential as a renewable platform chemical for 12 industrial added-value compounds within e.g. polymer chemistry. Herein, we report a catalytic benign 13 transesterification method for the synthesis of MVG ester derivatives of trimethylolpropane (TMP) and pentaerythritol (PE). The secondary alcohol group of MVG greatly complicates the reaction and requires 14 15 a highly selective catalyst to push the reaction towards high conversion while avoiding polymerization. 16 Thus, a range of different catalytic systems, e.g. Candida Antarctica Lipase B (CALB), Brønsted bases/acids, 17 salicylic aldehyde as well as Lewis acids were evaluated for the reaction. Despite the challenges this leads 18 to unique derivatives of TMP and PE with an additional chemical handle compared to classic derivatives 19 like the methacrylate and mercaptopropionate.

23 **1. Introduction**

The progressing depletion of fossil fuels and increasing environmental concern demands design and development of novel bio-sustainable materials and chemicals. Currently, hemi-cellulose and sugar crops provide great potential as sustainable carbon sources. The ample functionality of biomass-derived sugars permits the synthesis of unique high functionality platform chemicals such as lactic acid, 5hydroxymethylfurfural, trans-2,5-dihydroxy-3-pentenoic acid methyl ester (DPM) and levulinic acid [1]. Unlike biofuels, these novel chemicals find application within niche markets and represent high-margin low-volume products [2].

31 Methyl vinyl glycolate (MVG) is another very interesting molecule within this type of renewable 32 platform chemicals. Despite MVGs small molecular structure, it possesses multiple functionalities 33 (hydroxyl, vinyl and ester) enabling a range of chemical modifications. Formation of MVG was discovered 34 by Holm, Saravanamurugan and Taarning [3] during examination of chemocatalytic (rather than 35 fermentation) routes for the synthesis of lactic acid derivatives from C6 sugars. The MVG was rationalized 36 to form via an initial retro-aldol reaction, which was supported by employing C4 sugar substrates where high yields, up to 55%, were obtained with Lewis acidic tin-based catalysts. This route of formation was 37 38 confirmed in a mechanistic study by Dusselier et al. [4].

Applications with MVG are so far relatively uncharted, however, its high functionality makes it interesting as a platform chemical, e.g. within polymer chemistry for the creation of unique materials. In this context, Sølvhøj, Taarning and Madsen [5] investigated both homo- and cross-metathesis reactions of MVG. Moreover, Dusselier et al. have studied the copolymerization of MVG and lactic acid, where an initial hydrolysis of MVG seemed to be necessary for the polymerization process [6]. Likewise, initial hydrolysis was also required when the homo-metathesis product (dimethyl-2,5-dihydroxy-345 hexenedioate) of MVG was investigated as a cross-linking agent within poly lactic acid (PLA) systems [7].
46 Despite these promising initial studies, new applications with MVG must be further developed to allow
47 the compound to become industrially relevant [8]. Hence, as part of our interest in synthesis of bio-based
48 chemicals [9] and design of new coating materials [10], we therefore set out to further develop the
49 chemistry of MVG. Herein, we present the first direct transesterification of MVG for the synthesis of a
50 new class of polyhydric alcohols derivatives; vinyl glycolic functionalized polyhydric alcohols.

51 MVG can be envisaged as propitious for a novel class of polyhydric alcohol derivatives with advanced 52 functionalities. Typical polyhydric alcohol derivatives like trimethylolpropane (TMP) ester derivatives of tris(3-mercaptopropionate) and triacrylate find use within coating chemistry [11]. These classical 53 54 derivatives only possess one functional group per branch, which upon curing, is lost. The secondary 55 alcohol group of MVG introduces an additional chemical handle, where further chemical transformations 56 are possible (Scheme 1). The ability to perform such manipulations is potentially highly valuable, as it 57 provides opportunities for property fine-tuning. Accordingly, we anticipate MVG derivatives to find 58 possible use in both coating systems, adhesives or as additives in formulations requiring a hydrophilic surface as well as in applications where functionalization of the hydroxyl groups provide specialized 59 60 polymer properties.

62 **Scheme 1.** Structures of the TMP derivatives TMP-VG (left), TMP-acrylate (center) and TMP-63 mercaptopropionate (right).

64 The synthesis of esters of TMP, and other polyols, are generally straightforward and prepared via a simple esterification process, albeit harsh conditions are necessary. Thus, typically is high temperature as 65 well as reduced pressure along with abundant excess of the corresponding carboxylic acid required to 66 67 achieve high yields [12][13]. These conditions are, unfortunately, unsuited when utilizing MVG as the secondary alcohol group may induce polymerization, which is further promoted with MVG in large excess. 68 69 Furthermore, is it considerably more attractive to perform the reaction under stoichiometric conditions. 70 MVG is surprisingly volatile despite its high boiling point ($T_b \sim 160$ °C), and this is probably the reason why 71 previous studies have hydrolyzed MVG to vinyl glycolic acid (VGA) prior to polymerization [6][7]. This further complicates the reaction, as high conversions are dependent on by-product removal. Thus, the 72 73 synthesis of branched MVG esters is highly dependent on an efficient chemoselective catalyst. In this 74 study, catalytic systems for the synthesis of MVG derivatives of TMP and pentaerythritol (PE) through 75 direct transesterification or esterification have been investigated (Scheme 2). Although the study evolves around the transesterification of MVG and polyhydric alcohols, the findings are transferable to other 76 transesterifications systems where the hydroxyl group of α -hydroxy acid esters evoke complications. 77

79

80 **2. Experimental**

81 **2.1. Materials**

82 MVG was kindly donated by Haldor Topsøe A/S, Candida Antarctica Lipase B (CALB) was kindly donated by Novozymes A/S and ethoxy-PE (Polyol4290) and ethoxy-TMP (Polyol3380) were kindly donated by 83 84 Perstorp. All other solvents, reagents and materials were obtained commercially and used without further purification unless otherwise stated. Dry toluene and DMSO were obtained by a PureSolv[™] MD-7 Solvent 85 86 Purification System from Innovative Technology with Al₂O₃ as stationary phase. Vacuum of about 10 mbar was generated with an oil pump (without a manometer), and applied for the equilibrium 87 esterification/transesterification reactions to facilitate byproduct and water removal. Anhydrous 88 propanol and t-butanol was obtained by storing over activated 4 Å molecular sieves at least 24 h prior to 89 90 use, according to standard laboratory procedure [14].

91 2.2. Methods

NMR spectroscopy was performed on a Bruker Ascend spectrometer with a Prodigy cryoprobe operating at 400 MHz for ¹H NMR and 101 MHz for ¹³C NMR. HSQC and HMBC analysis where conducted for structure validation when ¹H and ¹³C NMR proved insufficient. All NMR spectra were recorded with d⁶-DMSO as solvent. Chemical shifts (δ) are reported in ppm downfield from TMS (δ = 0 ppm) using solvent resonance as the internal standard (¹H: 2.51 ppm, ¹³C: 39.52 ppm). First order coupling constants (*J*) are reported in Hz when applicable. Multiplicities are reported as singlet (s), doublet (d), triplet (t), quartet (q) doublet of doublets (dd), doublet of triplets (dt) and multiplets (m).

Infrared spectra were recorded on a Bruker alpha-P FT-IR spectrometer with 4 cm⁻¹ resolution. Peaks
 are reported as strong intensity (s), medium intensity (m), weak intensity (w) and broad peaks (b).

101 **2.3. Syntheses**

102 Vinyl glycolic acid (VGA)

103 A 10 mL round bottom flask was charged with MVG (4 mmol), CALB (50 mg) and 5 mL distilled water. The 104 mixture was then magnetically stirred with a stirring bar at 60 °C for 18 h (TLC indicated the reaction was 105 finished), where after the enzymes were removed by filtration followed by the water by rotary evaporation yielding a yellowish liquid in quantitative yields. ¹H NMR (400 MHz, d⁶-DMSO) δ/ppm: 5.94 106 107 (ddd, J = 17.2, 10.4, 4.9 Hz, 1H, HC-OH), 5.36 (dd, J = 17.3, 1.9 Hz, 1H, HCH), 5.16 (dt, J = 10.5, 1.9 Hz, 1H, HC*H*), 4.51 (dt, *J* = 5.0, 1.9 Hz, 1H, C*H*). ¹³C NMR (101 MHz, d⁶-DMSO) δ/ppm: 174 (COO), 137 (CH), 116 108 109 (HCH) and 71.5 (HC-OH). FTIR v/cm⁻¹: 2500- 3392 (s,b O-H stretch), 1718 (s, C=O stretch), 1642 (w, C=C 110 stretch), 1211 (m, C-O stretch), 1138 (m, C-O stretch), 1071 (m, C-O stretch), 990 cm⁻¹ (w, C=C-H oop).

111 Ethoxylated PE/TMP (ethoxy-PE/ethoxy-TMP)

112 A 10 mL round bottom flask was charged with MVG (4 mmol) and ethoxy-PE (Polyol 4290, 0.25 mmol) or 113 ethoxy-TMP (Polyol3380, 0.25 mmol), CALB (50 mg) and 5 mL anhydrous toluene. A tube with activated 4 114 Å molecular sieves was positioned on the flask, and the flask filled with N₂ gas after two vacuum cycles. 115 Subsequently, the mixture was magnetically stirring with a stirring bar for 70 h (¹H NMR indicated the reaction was finished by the peak appearing at 4.2 ppm). After reaction, the enzymes were removed by 116 117 filtration (by addition of acetone) and the toluene removed by rotary evaporation (40 °C, 50 mbar) to 118 obtain a transparent yellowish oil. Yield MVG-ethoxy-PE 83% (¹³C NMR relative to ethoxy-PE). Yield MVGethoxy-TMP 80% (¹H NMR relative to ethoxy-TMG). 119

120 TMP-VG

Method using VGA and tin(II) chloride: VGA (4 mmol), TMP (1 mmol) and SnCl₂·2H₂O (10 mg) was magnetically stirred in a 5 mL round bottom flask at 60 °C under vacuum for 40 h (¹H NMR indicated the reaction was finished by the peak appearing at 4.05 ppm). Yield 87.5% (¹³C NMR relative to TMP).

Method using MVG and tin(II) chloride: MVG (8 mmol), TMP (1 mmol) and SnCl₂·2H₂O (10 mg, 1 mmol) was added to a 5 mL round bottom flask and the mixture magnetically stirred in closed system at 120 °C for 18 h (¹H NMR indicated the reaction was finished by the peak appearing at 4.05 ppm). Conversion 65% (¹³C NMR relative to TMP).

Method using salicylic aldehyde: A 5 mL round bottom flask was charged with VGA (2 mmol), TMP (0.25 mmol), salicylic aldehyde (0.2 mmol) and 1 mL anhydrous toluene. The solution was purged with N₂ and subsequently magnetically stirred at 100 °C for 14 h (¹H NMR indicated full TMP conversion by the peak disappearing at 3.35 ppm). Yield 100% (¹³C NMR relative to TMP).

The products were purified by flash column chromatography with ethyl acetate:heptane (1:1) as eluent. 132 ¹H NMR (400 MHz, d⁶-DMSO) δ/ppm 5.98-5.83 (m, *3.5 H*, CH), 5.75 (d, *J* = 6.1 Hz, *2H*, OH) ,5.56-5.45 (m, 133 134 1H, CH-oligomer) 5.37 (dt, J = 17.2, 1.8 Hz, 3H, HCH), 5.19 (dt, J = 10.4, 1.6 Hz, , 3H, HCH), 4.7 (m, 0.5 H, HC-OH, oligomer), 4.6 (m, 0.5 H, HC-OH), 4.09-3.97 (m, 6H C(CH₂O-)₃), 1.41 (q, J = 7.6 Hz, 2H CCH₂CH₃) and 135 0.84-0.78 (m, 3H, CCH₂CH₃). ¹³C NMR (101 MHz, d⁶-DMSO) δ/ppm 172.38 (COO), 136.14 (HC), 116.72 136 137 (HCH), 71.47 (HC-OH), 64.09 (C(CH₂O-)₃), 41.27 (quaternary carbon), 22.73 (CCH₂CH₃), 7.66 (CH₃). FTIR v/cm^{-1} : 3373 (m,w O-H stretch), 2969 (w, C-H stretch of sp³ carbon), 1735 (s, C=O stretch of ester), 1644 138 (w, C=C stretch of vinyl), 1464 (w, CH₂ bend), 1387 (w, CH₃ bend), 1190 (s, C-O stretch), 1135 (s, C-O stretch), 139 140 1088 (s, C-O stretch), 987 (s, =C-H oop of vinyl), 932 (s, =C-H oop of vinyl).

141 Transesterification of MVG with TMP using Lewis acids

142 20 mL glass tubes were charged with TMP (0.5 mmol), MVG (4 mmol) and a metal chloride (0.02 mmol). 143 The glass tubes were evacuated to vacuum and positioned in a Carousel 12 Plus Reaction Station[™] that 144 was preheated to 120 °C and stirred. During reaction (12 h), the tubes were shortly removed from the 145 carousel every 4 h to take small samples (~0.05 mL) by a syringe, which were added directly to d⁶-DMSO 146 in NMR tubes and stored in a fridge prior to analysis. Samples from reaction with FeCl₂ and YbCl₃ were 147 filtered prior to analysis to avoid severe signal broadening from metal ions.

148 Transesterification of MVG with TMP/PE using tin(II) chloride

Typically 10 mL round bottom flask was charged with MVG (12 mmol), TMP/PE (1.5 mmol), SnCl₂·2H₂O (15 mg, 1.5 mmol) and evacuated to vacuum, where after it was placed in an oil bath at 120 °C with magnetically stirring. During reaction, aliquots of the reaction mixture (~0.05 mL) were periodically syringed, and added to d⁶-DMSO in NMR tubes. All samples were stored in a fridge prior to NMR analysis.

153 3. Results and Discussion

3.1. Analytic method for transesterification reactions

155 In order to evaluate the transesterification reactions comprehensibly, a reliable method for determination 156 of conversion as well as the degree of acylation and oligomerization was necessary. Such analysis is not common practice within these types of reactions, however it was noticed that acylation moves the 157 chemical shift of the quaternary carbon in ¹³C NMR sufficiently upfield to identify each individual species. 158 Through comparison between standard and quantitative ¹³C NMR it was found that standard ¹³C NMR was 159 160 adequate, both for the determination of conversion and acylation degree based on integration of the 161 quaternary carbons. By conducting HSQC and HMBC experiments, it was found that the degree of 162 polymerization could be determined by ¹H NMR (see SI for detailed description).

163 **3.2.** Candida Antarctica Lipase B (CALB) catalyzed transesterification

164 The transesterification of MVG and TMP/PE requires high chemoselectivity, especially for primary alcohols 165 over secondary alcohols. Enzymes have emerged as sustainable catalysts with high regio- and 166 enantioselectivity and Candida Antarctica Lipase B (CALB) has been extensively studied for the selective 167 acylation of sugars with high selectivity reported towards the acylation of primary hydroxyl groups 168 [15,[16], while it also tolerates other functional groups such as vinyl or acrylic double bonds [17]. 169 Moreover, secondary alcohols in the α -position to the acyl donor are generally not reactive in CALBcatalyzed acylations [18], [19]. CALB is further known to catalyze the acylation of polyols and the 170 171 transesterification of α -hydroxy acids, thus potentially making it an ideal catalyst for the present study 172 [20],[21].

173 When carrying out the CALB catalyzed transesterification between MVG and TMP or PE low product yield 174 was observed (Table 1, entry 1). However, CALB was able to catalyze the transesterification between propanol 175 and MVG (result not shown), thereby proving that CALB was able to catalyze the transesterification with MVG 176 as acyl donor and it is also known to catalyze the acylation of glycerol and pentaerythritol in preparation of 177 branched molecules [22],[23]. Accordingly, it was rationalized that CALBs inability to catalyze the 178 transesterification between MVG and TMP/PE was due to steric constrains within the active center of the 179 enzyme. We hypothesized that by extending the length of the polyol branches the individual branches could 180 enter the active site of the enzyme while the rest of molecule stays outside. Thus, the hydroxyl groups become 181 more available for the enzyme despite the molecule becomes more sterically demanding at the core. When 182 changing the polyols to the analogous ethoxylated adducts, up to 80% transesterification yields were obtained 183 using just a 4 times molar excess of MVG in toluene (Table 1, entries 2 and 4). This supports the hypothesis 184 that steric properties is a main issue for the reaction with polyols like TMP and PE. The ethoxylation further 185 reduces the polarity and changes the physical state of the substrate (oils rather than solids) allowing for 186 conducting the reaction in bulk. Unfortunately, when carrying out the reaction in bulk MVG (15-fold excess) no

conversion was observed (Table 1, entry 3), indicating that MVG inactivates the enzyme as is common with highly solvating molecules like DMSO and DMF [24]. This effect combined with the high viscosity of ethoxylated polyols and low reaction temperatures makes CALB unsuitable for carrying out this reaction without solvents. Surprisingly, a small degree of oligomerization was observed despite CALB - according to the literature [18],[21] - cannot polymerize α-hydroxy acids.

194 **3.3. Brønsted base/acid catalyzed transesterification**

193

Homogeneous base catalysis is superior in the transesterifications reactions of biodiesel [25]. However,
 bases are generally highly sensitive towards acid and water impurities, and the applied MVG contained
 VGA impurities (~3.3% determined by ¹H NMR). As MVG is also reported to dimerize with equimolar

amounts of base, it was not surprising that the transesterification of MVG with propanol did not proceedwith 5 mol% KOH.

Transesterification of, e.g. biodiesel, is also widely applied using homogeneous acid catalysis due to the robustness of acids against typical impurities (acid and water) [25]. In line with this, sulfuric acid actively catalyzed the transesterification between MVG and propanol (Table 1, entry 5), but unfortunately also produced copious amounts of unwanted byproducts in high yields making the system useless.

204 3.4. Salicylic aldehyde catalyzed (trans)esterification

205 Outside of the typical transesterification catalysts, salicylic aldehyde has been found to irreversibly 206 catalyze the esterification process of α -hydroxy acids [26]. Salicylic aldehyde proved very efficient in 207 catalyzing the esterification process between VGA and TMP resulting in quantitative yield with only 2.66 208 times VGA excess (Table 1, entry 6). This is quite impressive as esterification reactions are typically carried 209 out with more than 10-fold excess of one of the substrates and removal of the produced byproducts to 210 obtain high conversions [27]. Unfortunately, salicylic aldehyde could not catalyze the process with MVG 211 as acyl donor, deeming it necessary to carry out a hydrolysis step to VGA before its eventual use. Although 212 the hydrolysis step potentially is easy to do also in a larger (industrial) setting, it would probably be 213 undesirable as it also introduces an accompanying energy consuming purification step.

214 **3.5. Lewis acid catalyzed transesterification**

215 Tin(II) chloride

We hypothesized that tin(II) chloride would be a good Lewis acid catalyst for this reaction as tin(II) compounds are known to be efficient Lewis acid catalysts for transesterification and esterification reactions and, as previously mentioned, co-polymerization of lactic acid and VGA was achieved using tin(II) 219 chloride [6], [27], [28]. When SnCl₂·2H₂O was used as catalyst for the esterification of MVG in the present 220 study, the reaction was also found to proceed quite selectively under benign conditions reaching full 221 conversion with equimolar amount of VGA and PE (based on OH groups) at 60 °C with vacuum in 43 h 222 (Table 1, entry 8), while higher temperatures led to undesired evaporation of VGA. Similarly, was the 223 triacylated TMP derivative also successfully synthesized (Table 1, entry 9). On the other hand, in the 224 transesterification MVG proved too volatile to carry out the direct transesterification under those 225 conditions (60 °C, vacuum), and only 45% conversion was reached after 74 h without the applied vacuum. 226 However, by increasing the reaction temperature to 120 °C it proved possible, in the closed system, to significantly increase the rate of the transesterification, while maintaining limited oligomerization and 227 228 MVG evaporation, and obtain 75% conversion within 13 h with just a 2.66-fold molar excess of MVG to 229 TMP (Table 1, entries 13 and 1 and Figure 1). Despite the reaction being solvent free, the reaction rate 230 appeared to be independent of the conversion as well as the acylation degree. Moreover, oligomerization 231 occurred only in miniscule amounts with average degree of polymerization (DP) below 1.3 and DP of 232 oligomerized MVG units stabilizing around 2, indicating that 20% of the MVG molecules had dimerized.

Figure 1. Product distribution plot of mono-, di- and triacylated TMP in the transesterification of MVG and
 TMP in closed system with tin(II) chloride as catalyst. Reaction conditions: 1.5 mol% SnCl₂·2H₂O, 2.66 MVG
 to TMP ratio (based on OH-groups), 120 °C.

237 Surprisingly, when carrying out the analogous tin(II) catalyzed transesterification reaction with PE the OH conversion reaches a plateau after approximately just 1 h albeit at a conversion of only about 50% 238 239 (Figure 2). Similarly, the reaction rate did apparently not change as function of conversion nor did the 240 acylation degree and oligomerization was negligible. In order to obtain higher conversion, vacuum-heat 241 cycles was attempted where evaporation of MVG was avoided by cooling the reaction mixture to room 242 temperature before applying vacuum for 2 h followed by 2 h stirring at 120 °C. The two first cycles 243 increased the conversion approximately 10% per cycle, but oligomerization increased simultaneously thus 244 providing a lower overall yield.

The rapid reaction kinetics of PE compared to TMP was unexpected considering the similarity of the molecules. The difference could possibly be a coordinative effect originating from the fourth hydroxyl group of PE, however, since the reaction rate was not dependent of the acylation degree (which should markedly affect the coordinative properties), the observed reactivity difference could be related to properties such as, e.g. solubility and viscosity (i.e. diffusion).

Figure 2. Product distribution plot of mono-, di-, tri- and tetraacylated PE in the transesterification of MVG and
 PE in closed system with tin(II) chloride as catalyst. Reaction conditions: 1.5 mol% SnCl₂·2H₂O, 2.66 MVG to PE
 ratio (based on OH-groups), 120 °C.

260 Alternative metal chlorides

261 The good performance of tin(II) chloride for the transesterification of MVG and TMP, without forming notable side products, prompted us to investigate other Lewis acidic metal chloride catalysts for the 262 263 reaction. Based on the good results of tin(II) chloride, the more acidic tin(IV) chloride was examined 264 despite it not being a typical transesterification catalyst [29], while aluminium(III) chloride, zinc(II) chloride and ytterbium(III) chloride was selected as they are more common Lewis acids. Chromium(III) chloride are 265 266 in rare and specific cases an efficient transesterification catalyst [30],[31], whereas iron(II) chloride was chosen to have an untypical transesterification catalyst in the study. The 13 C NMR signal pattern in the δ 267 40-46 ppm range was characteristic for the MVG-TMP product mixture obtained in the tin catalyzed 268 269 reactions (Figure 3), and allowed to estimate the conversions for the other metal chlorides. The additional signals at δ 159-164 ppm were indicate of the byproducts. 270

278

Figure 3. ¹³C NMR spectra of the products after transesterification between MVG and TMP in closed system with various metal chloride catalysts. Reaction conditions: 1.33 mol% metal chloride, 2.66 MVG to TMP ratio (based on OH-groups), 120 °C, 12 h.

282 As summarized in Figure 4, most of the catalysts based on alternative metals than tin yielded only 283 moderate conversions in the reaction as well as a range of byproducts (unidentified), as also found for 284 H_2SO_4 (see above) though even more prominent. The lower catalytic activity observed for these catalysts, 285 including the strong Lewis acid aluminum(III) chloride which performed quite poor, could be related to 286 their limited solubility as only the tin halides efficiently dissolved in the TMP/MVG media under the applied reaction conditions. Thus, unfortunately the difference in solubility complicated the direct 287 comparison between activity and acidity. Nevertheless, it was evident that tin chlorides was superior for 288 289 this reaction. Notably, tin(IV) chloride was apparently found to be significantly more active than tin(II) 290 chloride for the reaction allowing it to reach a final product yield of ~75% within 4-8 h instead of 12 h. 291 This could be correlated to tin(IV) being a stronger Lewis acid and harder metal species than tin(II), thereby 292 facilitating reaction with the oxygen-rich substrates. Interestingly, similar superior reactivity of 293 tin(IV)/tin(II) salts have also previously been found in formation of α -hydroxy acids from tetroses [4]. The 294 superior performance of the tin chlorides was partly ascribed to their complete dissolution in the reaction 295 mixture (see above). Thus, if presence of tin chloride is undesired in the product a filtration through silica 296 with an appropriate solvent would be necessary. However, this would make reusability of the catalyst cumbersome and a further development of the process could therefore instead target investigation of a 297 298 suitable heterogeneous tin catalyst, where catalyst recycling is easy by simple filtration.

 Reaction conditions: 1.33 mol% catalyst, 2.66 MVG to TMP ratio (based on OH-groups), 120 °C.

309 4. Conclusions

310 A catalytic and benign method for the synthesis of a unique class of polyhydric derivatives - with multiple 311 functionalities - based on the novel bio-based molecule MVG were successfully developed. Salicylic aldehyde catalyzed the esterification process to provide the triacylated VG derivative of TMP in excellent 312 yield with negligible oligomerization from VGA. Tin chlorides efficiently catalyzed the direct 313 314 transesterification process from MVG, whereas other Lewis acidic metal chlorides provided low activity 315 and selectivity. Furthermore, CALB was found to catalyze the transesterification process with ethoxylated 316 polyols, albeit high MVG concentrations inactivated the enzyme. Overall, the reported work demonstrates 317 that novel MVG derivatives of polyols can be synthesized with negligible oligomerization under benign and solvent free conditions with low MVG excess by use of catalysts with tin(IV) chloride being superior. 318 319 The new MVG derivatives with a secondary hydroxyl group could possibly find use in coating systems,

- 320 adhesives or as additives, where a hydrophilic surface is required or the hydroxyl groups functionalized to
- 321 comply with other specialized polymer properties.
