1 **ABSTRACT**

2 **Background:** Monoacylglycerols (MAG) containing polyunsaturated fatty acids
3 (PUFA), especially, eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA),
4 have interesting applications. The enzymatic processing of such MAG directly from
5 fish oils is highly interesting integrating the processing of MAG and concentration of
6 EPA and DHA. The aim of this study was then to develop an efficient enzymatic
7 glycerolysis system together with physical fractionation for the production of PUFA-
8 MAG from tuna oil. **Results:** Novozym 435 was eventually selected after evaluation
9 together with the immobilized Lipase AK in tertiary alcohol based system. A further
10 evaluation of solvent mixtures involving tertiary alcohols was made, taking the
11 consideration of operation easiness. It turned out that a number of mixtures gave
12 similar performances as *tert*-butanol (TB). Basic reaction parameters were thoroughly
13 evaluated. In the batch reaction system with TB as solvent, the recommended
14 conditions were: glycerol/tuna oil 4:1 mol/mol, TB/tuna oil 2:1 wt/wt, 15 wt%
15 Novozym 435, and temperature 40 °C. Under these conditions, the yield of MAG was
16 up to 90% after 3 h incubation. Crude MAG from the production was fractionated to
17 produce MAG with higher EPA and DHA content. Using acetone as solvent at 0 °C
18 led to ca. 50% yield of MAG but contained EPA and DHA up to 71% in comparison
19 with ca. 30% in tuna oil. **Conclusion:** Potentially practical process steps have been
20 developed for the production of MAG containing high content of EPA and DHA from
21 natural fish oils with high efficiency and simplicity.

22 **Keywords:** Monoacylglycerols, glycerolysis, fractionation, polyunsaturated fatty acid
23 (PUFA), Novozym 435, tuna oil

1 INTRODUCTION

2 Monoacylglycerols (MAG) or mixtures with diacylglycerols (DAG) account
3 for approximately 75% of the emulsifier production and have applications in different
4 fields.¹⁻³ In the food industry, MAG are widely used in bakery products, margarines,
5 dairy products, and confectionary because of their emulsifying, stabilizing, and
6 conditioning properties. They are also important in cosmetic and pharmaceutical
7 industries as drug carriers and for consistency improvements in creams and lotions.
8 Commercial food MAG are manufactured by chemical glycerolysis of fats and oils.
9 High temperature (220-250 °C) and inorganic alkaline catalysts are used to accelerate
10 the reactions. These chemical and physical processes are not suitable for heat-
11 sensitive oils and fats because of potential deleterious effects on nutritional and
12 biological properties.

13 Lipase-catalyzed glycerolysis of fats and oils at atmospheric pressure and low
14 temperature has attracted interest in both academia and industry as a practical
15 alternative to chemical methods in the production of commercial MAG. Several
16 glycerolysis systems have been investigated with or without organic solvents, with
17 immobilized or non-immobilized enzymes, and in microemulsion or other media.³⁻⁴

18 Glycerolysis system with an immobilized lipase as catalyst is a three-phase
19 system: a hydrophobic oil phase, a hydrophilic glycerol phase, and a solid enzyme
20 phase. Because of the more hydrophilic characteristics of the enzyme, glycerol often
21 binds to enzyme particles so that the access of oil molecules to the enzyme is difficult.
22 The mass transfer of glycerol is also limited. Thus the reaction efficiency is usually
23 low even though the efficiency can be improved through optimization in a narrow
24 range. It is reported that glycerol can be immobilized on silica gel so as to overcome

1 these problems.^{1,4} The improvement is only minor, however, not to say difficulties in
2 practical operations. Therefore, a solvent medium is actually an important solution to
3 improve the homogeneity of the system.

4 A single solvent that can dissolve oil and glycerol in a homogeneous system is
5 actually very difficult to find. The hydrocarbon solvents were generally impossible for
6 this purpose. After evaluation, a few alcohols with more than five carbons can be
7 considered since they contain a polar hydroxyl group and a nonpolar carbon chain.
8 However, alcohols are naturally reaction competitors to glycerol, especially the
9 primary alcohols. From the study of Damstrup *et al.*² and Yang *et al.*⁵, the use of
10 tertiary alcohols is possible and does not involve in reactions with fatty acids, most
11 likely due to the tertiary structure of the alcohols, which exerts strong steric hindrance
12 to the enzyme in the system. Therefore, TB or *tert*-pentanol (TP) is promising for the
13 glycerolysis system. Higher yield of MAG has been achieved with tertiary alcohols in
14 the glycerolysis system^{2,5}.

15 Omega-3 PUFA have received much attention in recent years because of the
16 health benefits they offer, including reduced risk of coronary disease, prevention of
17 certain cancers, and improved immune function.^{6,7} Omega-3 PUFA-containing MAG
18 are interesting for many potential uses or applications in food, drug, or cosmetic
19 production. Their MAG forms may offer new possibilities in different applications.
20 We have intended to synthesize MAG from fish oil with higher content of omega-3
21 PUFA through alcoholysis of fish oil with 1,3-specific lipases.^{8,9} The reaction strategy
22 was mainly to produce 2-MAG since usually more omega-3 PUFA is located at 2-
23 position of fish oil.^{6,8}

One possible approach to obtain a dedicated fraction with different melting points is the application of fractionation. There are several approaches available to fractionate fats and oils including dry fractionation (without solvent), wet fractionation (with solvent), and super-critical fluid fractionation.^{10,11} Using these fractionation processes, lipid fractions with different nutritive properties can be produced since the melting behavior of lipids is strongly related to the number of double bonds, meaning PUFA fractions and their derivatives can have very different melting properties from the rest fractions in the mixture.

Therefore, in this study, we designed the production of MAG rich in omega-3 PUFA (EPA and DHA) into a two-step operation. In the first step, an efficient glycerolysis system should be set up for the enzymatic production of MAG from fish oil. The system with tertiary alcohols was considered for the above consideration, as high yields of MAG can be expected in the system after optimization.^{2,5} Under such a possibility, the second step was targeted to fractionate the MAG containing PUFA. Normally, such MAG have much lower melting points than MAG containing saturated or monounsaturated fatty acids. Therefore, a physical fractionation system was also studied to isolate the omega-3 PUFA containing MAG from other MAG.

MATERIALS

Crude tuna oil from Skipjack tuna head, with water content of 4.4% and free fatty acid content of 0.36%, was provided by Chotiwat Industrial Co. Ltd. (Hat Yai, Thailand). The oil was prepared from crude tuna oil by a conventional pressing method. The refined oil was achieved through degumming, neutralization, bleaching, and deodorizing. The major fatty acid compositions of the refined oil (wt%) was as following: C14:0, C16:0, C18:0, C18:1, C18:2, C20:5 and C22:6 (4.2, 30.6, 9.3, 17.3, 2.6, 6.7 and 29.0, respectively). The glycerol was analytical grade with 0.2% water.

1 The properties of TB are boiling point 83 °C, melting point 25 °C, relative density
2 (water=1) 0.8, octanol/water partition coefficient ($\log P_{o/w}$) 0.4, and with colorless
3 appearance. Commercially immobilized lipase, Novozym 435, from *Candida*
4 *antarctica* lipase B, was obtained from Novozymes (Bagsvaerd, Denmark) and
5 *Pseudomonas fluorescens* lipase (Lipase AK) was a gift from Amano Pharmaceutical
6 Co. Ltd (Nagoya, Japan). Accurel EP-100, a microporous polypropylene powder
7 (particle size < 400 μm), was a gift from Akzo Nobel Membrana (Obernburg,
8 Germany). All other chemicals and solvents used were of reagent grade or analytical
9 grade.

10 **METHODS**

11 *Preparation of the immobilized lipase*

12 Accurel EP-100 (10 g) was added to 100 mL of buffer (pH 7) containing 100
13 U/mL Lipase AK and the mixture was stirred with a magnetic bar at 100 rpm for 30
14 min. Afterward, 100 ml of 0.1M phosphate buffer (pH 7) was added and the
15 suspension was filtered through a Buchner funnel by vacuum. The immobilized
16 enzyme (IM-AK) was washed with 100 mL of 0.1M phosphate buffer to remove the
17 unbound enzyme.

18 The water content of the immobilized enzyme was adjusted by different
19 methods¹². The first method was vacuum drying in a desiccator at room temperature
20 for 12 h ($a_w=0.389$). The second method was acetone washing and evaporation
21 ($a_w=0.019$). And the last method was to equilibrate the enzyme over saturated LiCl
22 solution in a desiccator at 25 °C for 16 h ($a_w=0.113$). The water activity (a_w) of the
23 prepared enzymes was measured with an Aqualab Water Activity Meter (Decagon
24 Devices, Inc., Washington, USA) at room temperature, as shown in the parenthesis.

Enzymatic glycerolysis of tuna oil

The mixture of 10 g of tuna oil, required amount of glycerol and TB was incubated in a capped 25-mL flask at the designed conditions on a 400 rpm shaker. The reaction was initiated by the addition of lipases. At selected intervals, 0.25 mL of reaction mixture was withdrawn and the lipase was removed by filtration and the solvent was removed by vacuum. All samples were stored at -20 °C before analysis. Experimental repeatability for batch reactions was conducted through three experiments under the following condition: temperature 45 °C, glycerol/tuna oil molar ratio 4.5:1.0, TB/tuna oil 2.2:1.0 (w/w), 15 wt% lipase (based on oil and glycerol), and no additional water.

Fractionation of PUFA-MAG from reaction mixture of glycerolysis of tuna oil

The product collected after reaction under the optimal conditions was subjected to solvent removal under vacuum and was named as crude MAG. The crude MAG in 0.1 g was dissolved in 30 mL of different solvents or mixtures. Acetone and hexane are commonly cited in the literature and used industrially. Therefore, these two solvents were selected together with one mixture between the two solvent in 50/50 (v/v). The fractionation was conducted under different temperatures. Based on melting points of different MAG fractions, the 10, 4, and 0 °C were selected for evaluation. The fractionation was conducted in a selected solvent and temperature for 3 h. Afterwards the samples were centrifuged at the same temperature for 30 min at 10000 rpm. The supernatant was removed and the solid was washed several times with the same solvent cooled to the same temperature. The liquid parts were collected together. The solvent was removed from both solids and liquids by a vacuum evaporator. The two fractions were then weighed and used for further analysis.

1 *Analysis of acylglycerols by TLC-FID*

2 The components of oil phase were analyzed with a thin-layer chromatography
3 with flame ionization detector (TLC/FID)(IATROSCAN MK5, Iatron Laboratories
4 Inc., Tokyo, Japan) for the content of TAG, 1,2(2,3)-DAG, 1,3-DAG, MAG and free
5 fatty acids (FFA).¹³ The samples diluted in chloroform/methanol (2:1 v/v) were
6 spotted onto the chromarod and developed for 35 min in a mixture of
7 benzene/chloroform/acetic acid (50:20:0.7, v/v/v). After developing and drying, the
8 rods were subjected to scanning with FID. Standards were used to identify the peaks.
9 The peaks areas were normalized and used for evaluation of reactions. Triplicate
10 analysis was conducted and the averages were used.

11 *Analysis of fatty acids compositions*

12 The fatty acid compositions of acylglycerol species were determined by
13 converting into fatty acids methyl esters followed by GC analysis. After evaporating
14 excess solvent of the sample, the mixture was applied to normal silica gel TLC-plate
15 and developed in benzene/chloroform/acetic acid (50:20:0.7, v/v/v). After drying, the
16 MAG band was scraped off and methylated with 0.5%NaOH in methanol (1000 μ L),
17 for 10 min at 60 °C. The methyl esters were extracted with *n*-hexane (300 μ L) for 1
18 min. The *n*-hexane layer was washed with 200 μ L distilled water and dried over
19 anhydrous sodium sulfate. Analysis was carried out with a Perkin-Elmer Autosystem
20 XL-GC gas chromatograph (Perkin-Elmer Corporation, Norwalk, CT) on a FFFAP
21 column (PERMABOND-FFFAP DF-0.25, 25m $\times$ 0.25mm *i.d.*, MACHEREY-NAGEL,
22 Germany). The carrier gas was helium at a flow rate of 0.5 mL/min (15 psi) and
23 operated in a split ratio of 50:1. The temperature was started from 150 °C for 0.50 min
24 and increased at the rate of 4 °C/min to 170 °C, followed with the rate of 5 °C/min to
25 195 °C, and further with the rate of 10 °C/min to and 215 °C and held there for 14

1 min. Injector and detector temperatures were 250 °C.¹⁴ Response factors were
2 determined using a standard mixture of fatty acid methyl esters. Duplicate analyses
3 were carried out for all samples. The relative standard deviation was less than 4.1%
4 for all results more than 10% and less than 6.6% for results less than 10%.

5 *Statistical analysis*

6 The SPSS program analysis was used for data analysis.¹⁵ Analysis of variance
7 and t-test were used to evaluate the significance and difference of data. Values were
8 considered significant at $P < 0.05$ level.

9 **RESULTS AND DISCUSSION**

10 *Selection of lipases for glycerolysis*

11 Enzyme characteristics can have determinant functions for the product
12 development and process development. In recent progress of enzymatic production of
13 MAG in solvent systems, Novozym 435 was recommended for the tertiary solvent
14 system.^{2,5} Kaewthong and H-Kittikun¹³, however, concluded from a solvent screening
15 that IM-AK showed good activity in the system used. To find an appropriate catalyst
16 for the aimed MAG processing, the two immobilized lipases concluded from the
17 above studies were selected for further evaluation, i.e. Novozym 435 from *Candida*
18 *antarctica* B lipase (nonspecific) with the hydrolytic activity of 9.8 U/mg
19 immobilized enzyme and IM-AK from *Pseudomonas fluorescens* lipase (1,3-specific
20 lipase) with the hydrolytic activity of 0.97 U/mg immobilized enzyme. In the TB and
21 hexane media, experiments were conducted at the ratio of organic solvent to tuna oil
22 2.2:1.0 (w/w), immobilized enzyme 100 U/g (based on total substrates), 4.5:1.0
23 (mol/mol) glycerol/tuna oil, 45 °C, and reaction time of 8 h. The results showed that
24 the reaction by both enzymes in hexane was slow with very low TAG conversion (less
25 than 20%), while in TB much more MAG were formed (data not shown). In TB,

1 Novozym 435 showed the highest activity with 90% yield of MAG, while IM-AK
2 gave 70% conversion but with 21% FFA (Fig. 1). High FFA content is a problem for
3 industrial applications. It obviously came from the higher water content in the
4 immobilized lipase. We therefore studied the pretreatment of the IM-AK to see if the
5 performance could be further improved because it could be a cheaper alternative to
6 Novozym 435. Therefore, the IM-AK was pre-treated to reduce the water content and
7 the following different water activities (a_w) were obtained as 0.369, 0.113, and 0.019.
8 As seen from Fig. 2, once water content was down, the activity of the immobilized
9 enzyme was decreased as well, meaning the enzyme was water dependent. This
10 implies that the lipase needs higher amount of water to maintain the activity, but such
11 a high amount of water will consequently lead to the stronger hydrolysis reaction so
12 as to form higher amount of FFA. This behavior makes difficult for the use of IM-AK
13 in such reactions where polar solvents are used to exert stronger water partitioning
14 from enzymes. Therefore we conclude that IM-AK is not quite suitable for the
15 reaction system even though quite good reaction conversion can be obtained in high
16 water content situations (Fig. 1). As widely demonstrated and also proved in this
17 study, Novozym 435 has less water dependence and its catalytic activity did not drop
18 even in very polar systems with ethanol.^{2,5,16} After all, Novozym 435 was selected for
19 further process studies, even though it is a costly commercial lipase. With its low
20 water requirement, the process can have high benefit, in which a very low FFA
21 content can be obtained in the products. This is a very important issue for industrial
22 applications since higher FFA content will lead to the loss of oils as well as difficulty
23 in processing.

Evaluations of solvent mixtures for glycerolysis of tuna oil

As demonstrated in a few recent publications,^{2,5} tertiary alcohols are suitable solvents for the efficient glycerolysis system with very short reaction time but high MAG yields. However, TB is solid in room temperature (melting point 25-26 °C) so as making the process operation difficult while TP is much more expensive (2-3 fold higher than TB). Therefore, a mixture could be a better choice for practical and cost-effective processes. Therefore the mixtures of the two solvents as well as the mixtures with hexane were evaluated for the reaction system to offer possibilities for different selections. The glycerolysis reaction was carried out in such solvent mixtures and their results are shown in Fig. 3. Tertiary alcohols and their mixtures generally gave higher yields of MAG, even though there were slightly differences between each other. The mixtures of tertiary alcohols with low amount of hexane (20%) also gave reasonably good result, but higher amount of hexane led to lower yields of MAG. Yields of MAG 90-95% were occurred in mixtures of TB/hexane (down to 20% v/v hexane) and TB/TP in various ratios (20:80, 50:50, and 80:20 v/v). This offers a variety of possibilities of solvent selection in practical uses. As seen from the studies of the different mixtures, particularly with tertiary alcohols, the reaction behavior is very similar each other in terms of reaction conversion and enzyme activity (Fig. 3 and data not shown). In practical uses, different decisions can be made depending on the easiness of the process and cost of the solvents as well as other subjective considerations. To simplify the study for the fractionation part, TB was selected for the following experiments since more information has been accumulated in large scale operations concerning TB evaporation procedures and its safety approval from the authority.

Evaluations of other parameters on the MAG yield

Various parameters for the reaction systems have been already evaluated in the early studies^{2,5}. Due to the use of tuna oil where contains high content of DHA and EPA in this study, we had concerns whether the reaction will be seriously affected since the early work used the linoleic acid dominated sunflower oil as materials^{2,5}. Therefore, we still made the evaluation of various parameters. After all, the effects of parameters with the use of tuna oil were very similar to those pervious studies (data not shown). Therefore only a general summary is given below. The effects of enzyme loading, amount of solvent, substrate ratio and temperature on the glycerolysis of tuna oil were performed. In the batch reactions, 15 wt% Novozym 435 based on total substrates (glycerol and oil) gave the maximum reaction performance and was used for further reactions. The weight ratio of TB to tuna oil of 2.0:1.0-2.5:1.0 showed high MAG production with no significant difference. Therefore, the weight ratio of TB to tuna oil of 2.0:1.0 was selected. For the effect of glycerol amount, the result showed that the molar substrate ratio of glycerol and oil of 4.0:1.0-4.5:1.0 had no significant difference on MAG production. Therefore, in this study, 4.0:1.0 (mol/mol) glycerol/tuna oil was decided. For the effect of temperature, glycerolysis of tuna oil was carried out at 30 to 50 °C and the results showed that the temperature of 40-50 °C showed high MAG production with no significant difference. Therefore, the temperature of 40 °C was selected for the production since lower temperature was recommended with respect to the product quality.

MAG production under optimal conditions

The recommended conditions for MAG production were finalized as using TB as the medium, the molar ratio of glycerol to tuna oil of 4.0:1.0, the weight ratio of TB to tuna oil with 2.0:1.0, using 15 wt% Novozym 435 (based on glycerol and tuna oil),

1 and no additional water. The temperature was controlled at 40 °C. Under these
2 conditions, the yield of MAG of 90.8 wt% was obtained after 3 h incubation and the
3 remained TAG was only 5.5 wt%. A time course under such production conditions is
4 also conducted (Fig. 4).

5 The major fatty acid compositions of the MAG fraction after separating by
6 thin layer chromatography were determined by gas chromatography as follows:
7 C14:0, C16:0, C18:1, C18:2, C20:5 and C22:6 (3.5, 29.7, 8.6, 17.1, 3.6, 6.3 and 30.5
8 wt%, respectively). The fatty acid compositions had no significant difference from
9 that of the original tuna oil. The result indicated that the reaction gave little fatty acid
10 selectivity for the formation of MAG. This is a reasonable conclusion since the
11 reaction was an interesterification process where positional and fatty acid selectivity
12 of the lipase will place no difference for the product formation.

13 *Fractionation of the reaction mixture from glycerolysis of tuna oil*

14 Temperature fractionation of fats or oils or their derivatives can be regarded as
15 a thermo-mechanical separation process and has been widely used in industry.
16 Individual species (for example TAG or MAG) for a given material are selectively
17 crystallized from the liquid phase at different temperatures. During cooling of the
18 liquid oil or melted material, the species with the highest melting point preferentially
19 crystallized, resulting in solid phase within the system. For natural fats and oils, they
20 are mostly complex mixtures of individual TAG that can contain from one to three
21 different fatty acyl residues on their glycerol backbone. Because of this there is the
22 large variation in the melting points of the TAG species, which complicates the
23 fractionation process.^{10,11} For MAG product, single fatty acid residue is attached to
24 glycerol backbone, the melting point profile is largely dependent on the fatty acids
25 attached. Therefore, a simple separation of MAG with different fatty acids having

1 different unsaturation is theoretically possible. In particular, EPA and DHA have 5-6
2 double bonds, the melting points of their MAG will be largely different from rest of
3 fatty acids in tuna oil. For this reason, a fractionation system with solvent used (so-
4 called wet fractionation) was studied.

5 Temperature is a critical issue for fractionation. Theoretically, MAG with
6 C16:0 to C18:0 have a melting point (mp) in the range between 69-75 °C under pure
7 lipid phase.¹¹ The C18:1 based MAG has a mp around 24 °C and C18:2 based MAG
8 around 9 °C. No information for the mp of EPA and DHA based MAG, but a melting
9 point much lower can be expected. Once solvent applied, the melting behavior is
10 completely different from pure lipid phase. Both solvent and concentration in the
11 solvent can have effect on the crystallization temperatures. Based on application of
12 wet fractionation in industry as well as literature,¹¹ three temperatures (0, 4, 10 °C)
13 were selected for this study.

14 Solvent is another issue. Acetone and hexane have been commonly applied in
15 industry and many previous studies. Considering the higher polarity of the material,
16 the polarity of solvent may have effects on the fractionation process. Therefore, both
17 solvents were selected for further evaluation including their mixtures.

18 The effects of solvent and temperature on yield and fatty acid compositions
19 were evaluated. Table 1 shows that percentage of EPA and DHA were higher in liquid
20 fraction than solid fraction. The yield of liquid fraction was decreasing in general with
21 the decreasing of temperature. Consequently, the EPA and DHA content in the MAG
22 of the liquid fraction was increasing. The effect of solvent mixing was not very
23 significant. There was a tendency that better fractionation was obtained in the acetone
24 system than in the hexane system. Yang *et al.*¹⁷ found that the percentage of saturated
25 fatty acid of stearin decreased with increasing solvent polarity, and percentage of EPA

1 and DHA increased with solvent polarity and fractionation temperature. Lee and
2 Foglia¹¹ also reported that fractionation with acetone at low temperature was effective
3 for enriching the monounsaturated fatty acid of chicken fat in the liquid fraction.
4 Yokochi *et al.*¹⁸ reported that the winterization process with acetone at -20 °C showed
5 higher separation efficiency for tri-unsaturated TAG into liquid fraction than the other
6 solvents.

7 In general, C16:0 and C18:0 were dramatically reduced in the liquid fraction
8 and increased in the solid fraction.^{11,12} The oleic acid was also changing but not highly
9 consistent. The crystallization of oleic acid based MAG may need further lower
10 temperature. As commonly known, the yield of the liquid fraction will be reduced
11 with the decreasing of the temperature. The loss of the liquid fraction which is trapped
12 by the solids, will also increase. With the present set-up, a liquid fraction with around
13 50% yield of MAG contained 70% EPA and DHA at 0 °C using acetone was
14 obtained.

15 **CONCLUSION**

16 Physicoenzymatic production of MAG containing PUFA especially EPA and
17 DHA was investigated. A few solvent mixtures were suitable for production of MAG
18 by using Novozym 435 as a catalyst in glycerolysis of tuna oil. A few reaction
19 parameters have been evaluated including solvent amount, substrate ratio, enzyme
20 load, and temperature. The yield of MAG up to 90.8% could be achieved with suitable
21 conditions. The temperature fractionation under different solvents was evaluated in
22 order to produce a fraction with higher content of EPA and DHA. Temperature was a
23 critical parameter for effective fractionation. A liquid fraction under 0 °C
24 fractionation could be obtained with around 70% EPA and DHA and in a yield of

1 MAG around 50%. A possibility of enriching the EPA and DHA into MAG has been
2 built.

3 **ACKNOWLEDGEMENTS**

4 The research support by the *Royal Golden Jubilee Program* (RGJ, Thailand) is
5 gratefully acknowledged. The authors would like to thank Chotiwat Industrial Co.
6 Ltd. (Hat Yai, Thailand) for providing crude tuna oil, Amano (Nagoya, Japan) for
7 Lipase AK and Novozymes (Bagsvaerd, Denmark) for Novozym 435, as well as,
8 Akzo Nobel Membrana for Accurel EP-100.

FIGURE CAPTIONS:

Fig. 1. Glycerolysis time courses of tuna oil in *tert*-butanol. Reaction conditions: temperature 45 °C, glycerol/tuna oil molar ratio 4.5:1.0, *tert*-butanol/tuna oil 2.2:1.0 (wt/wt), 15 wt% lipases (based on total substrates), and no additional water. *Abbreviations:* TAG (triacylglycerol), DAG (diacylglycerol), MAG (monoacylglycerol), FFA (free fatty acid), AK (Immobilized lipase AK), 435 (Novozym 435)

Fig. 2. Glycerolysis time courses of tuna oil in *tert*-butanol by immobilized lipase AK (a). dry with acetone (b) adjusted water content with $a_w = 0.113$ by saturated salt (LiCl) (c). dry in vacuum. Reaction conditions: temperature 45 °C, glycerol/oil molar ratio 4.5:1.0, *tert*-butanol/oil 2.2:1.0 (w/w), 15 wt% Immobilized Lipase AK (based total substrates) and no additional water. See *Fig. 1* for abbreviations.

Fig. 3. Effects of solvent mixtures on glycerolysis of tuna oil. Reaction conditions: temperature 45 °C, glycerol/tuna oil molar ratio 4.5:1.0, reaction time 3 h, 15 wt% Novozym 435 (based on total substrates) and no additional water.

Fig. 4. Time course of glycerolysis by Novozym 435 in TB. The reaction mixture contained the mole ratio of glycerol to tuna oil with 4.0:1.0, the weight ratio of TB to tuna oil with 2.0:1.0, reaction time 3 h, 15 wt% Novozym 435 (based on glycerol and tuna oil) and no additional water.
