ARTICLE INFO

Keywords: Daphne mezereum Polysaccharides Pectin PBMC TNF-α IFN-γ

ABSTRACT

Daphne mezereum L., an important medicinal plant in Scandinavian folk medicine, was used to treat ailments such as diarrhea, swelling and stomach pain. A range of natural compounds have been isolated, but little attention has been given to the polysaccharides in this plant. Previous work in our group have shown that a polysaccharide enriched fraction from the bark of *D. mezereum* exhibited pro-inflammatory effects. To pursue this further, the aim of the present work was to isolate and characterize these polysaccharides. From the ethanol-precipitate of a water extract, one neutral (DMP-NF) and one acidic (DMP-AF) fraction was isolated by anion-exchange chromatography. GC, GC–MS and 1D- and 2D-NMR were used to characterize the polysaccharide structures. DMP-NF appeared to be a mixture of arabinan, arabinogalactan and hemicelluloses such as xyloglucan, mannan and xylan. DMP-AF contained a pectic polysaccharide mainly consisting of an unusually long homogalacturonan backbone. Enzymatic treatment by pectinase of DMP-AF yielded DMP-ED, which contained a rhamnogalacturonan-I backbone with arabinan, galactan and arabinogalactan side chains. Both DMP-NF and DMP-ED induced IFN-γ and TNF-α secretion in peripheral blood mononuclear cells (PBMCs), DMP-ED being the most potent fraction. DMP-AF was less active, which might be due to a less sterically available rhamnogalacturonan-I domain.

1. Introduction

In Scandinavian folk medicine, *Daphne mezereum* L. is regarded as an important medicinal plant. Despite its toxicity, infusion of *D. mezereum* was used against several ailments and diseases, such as diarrhea, swelling, stomach pain and tuberculosis (Høeg, 1974; Ulriksen et al., 2022). In addition to Scandinavia, the plant is also native to most of Europe and Western Asia (Moshiashvili, Tabatadze, & Mshvildadze, 2020). Several compounds from *D. mezereum* have been isolated and characterized, such as the coumarin glycosides triumbellin (Kreher, Wagner, & Neszmélyi, 1990), daphnorin (Tschesche, Schacht, & Legler, 1963), and the diterpene esters gniditrin (Görick & Melzig, 2013) and mezerein (Kupchan & Baxter, 1975). However, the polysaccharides from the Daphne genus have been given little attention.

Polysaccharides are a group of biopolymers that has gained an increased interest due to their interesting biological properties. This includes antitumor (Huang, Chen, Yang, & Huang, 2021), immunomodulatory (Gao et al., 2020) and antiviral (T. Wang et al., 2020) activity. For instance, the β -glucan lentinan extracted from the medicinal mushroom *Lentinula edodes* (Shiitake), has shown improved overall response rates against lung cancer in combination with chemotherapy due to its ability to stimulate immune cells (Y. Zhang et al., 2018). Another type of polysaccharide that is studied extensively for immunomodulatory effects is plant-derived pectins.

Pectins are a group of polysaccharides found in the middle lamella or the primary and secondary cell wall in plants. They are characterized by their high content of D-galacturonic acid (GalA). The backbone of pectins is suggested to consist of linear homogalacturonan (HG) and two branched rhamnogalacturonan (RG) regions, namely RG-I and RG-II (Wusigale, Liang, & Luo, 2020). In the HG-region, the partially acetylated or methyl-esterified GalA units are α -(1,4)-linked. In the RG-I region, the backbone is made up of rhamnose (Rha) and GalA residues that

are linked in the following manner: $[-4)-\alpha$ -D-GalA-(1,2)- α -L-Rha-(1]_n. Branching occurs at the O4-position of the rhamnose units. These side chains may be arabinans, galactans or arabinogalactans (Maxwell, Belshaw, Waldron, & Morris, 2012). The RG-II region on the other hand consists of minimum eight α -(1,4)-GalA units. It is a highly complexed branched region which consists of unusual sugars such as apiose, 2-*O* methyl fucose and 3-deoxy-D-manno-2-octulsonic acid (Bonnin, Garnier, & Ralet, 2014).

Immunomodulation by pectins may occur in a direct manner or indirectly through their role as dietary fibers. Pectins are not degraded by either human saliva, gastric acid or by human digestive system, and are therefore transferred undigested to the colon. Here, the gut microbiota degrades the pectin into the short fatty acids acetate, propionate and butyrate, all of which have displayed health promoting benefits (Koropatkin, Cameron, & Martens, 2012). Butyrate, for instance, is thought to exert modulatory effects on gut immune function (Siddiqui & Cresci, 2021). Further, by interacting with toll like receptors (TLRs), a type of pattern recognition receptors (PRRs) on immune cells, pectins can directly affect the immune cell response. A study on pectins with low degree of methyl esterification (DM) suggested that they may inhibit the pro-inflammatory TLR2-TLR1 pathway by binding to TLR2 through electrostatic interactions between non-esterified galacturonic acids on the pectin and positive charges on the TLR2 ectodomain (Sahasrabudhe et al., 2018). However, the TLR2-TLR6 pathway did not appear to be affected by this, which is probably due to hydrophobic interactions being predominant in this pathway.

A recent study indicated that pectins may also activate macrophages by interacting with TLR4 and complement receptor 3. By interacting with TLR4, the pectin activates myeloid differentiation protein 88 through IL-1 receptor kinase, followed by activation of TNF-receptor associated factor, MAPKs and NF- κ B. The latter two are also activated by complement receptor 3, but through the activation of phosphoinositide-3-kinase and protein kinase C. The overall effect of the pectic interactions led to enhanced phagocytosis and pinocytosis, in addition to the release of IL-1 β , TNF- α , IL-6 and NO (Huang et al., 2021). Other studies have also obtained similar results (H. Wang et al., 2018; Wang et al., 2019). Pectins with both a low and a high DM have been reported to activate TLR4 (Prado et al., 2020).

Earlier studies have shown that a crude polysaccharide extract from *Daphne pseudogenkwa* exhibits interesting antitumor properties (Moon, Park, Lee, & Yoon, 1985). Furthermore, we have preliminary results of a polysaccharide enriched fraction from *D. mezereum* showing promising stimulatory effects of macrophages and peripheral blood mononuclear cells (PBMCs) (Ulriksen et al., 2022). The fraction contained significant amounts of GalA, in addition to the presence of arabinose (Ara) and galactose (Gal), which could indicate the presence of pectic polysaccharides. However, no detailed structural characterization of purified polysaccharides from *D. mezereum* exist. Based on this, the aim of this study was to further isolate and structurally characterize polysaccharides from *D. mezereum*, and explore their immunostimulant effects on human PBMCs.

2. Methods

2.1. Plant material

Bark from *Daphne mezereum* L. (family: Thymelaeaceae) was collected 15.04.21, near Sognsvann in Oslo (59°57′55"N 10°42′30″E), Norway and its identity was verified by associate professor Anneleen Kool (Natural History Museum, UiO, Norway). The bark was airdried and pulverized using a kitchen blender (Vitamix A2300i). A voucher specimen with number RL-202120415-dm was deposited at the Natural History Museum herbarium.

2.2. Extraction of polysaccharides

A water extract of the plant material was obtained using an accelerated solvent extraction (ASE) 350 instrument (Dionex, Sunnyvale, CA, USA) at 100 °C with dH₂O as extraction solvent. Each cell was filled with 10 g of plant material and extracted twice with dH₂O. The water extract was applied to a Diaion HP-20 column (5×50 cm) and eluted with three column volumes of dH₂O. The obtained water fraction was further added 3-fold volumes of ethanol and kept at 4 °C for 48 h in order to precipitate the polysaccharides. The precipitate was washed with ethanol, centrifuged (4400 rpm, 20 min) and filtrated using a Büchner funnel. The precipitate was washed with ethanol, centrifuged (4400 rpm, 5 min) and filtrated again. Finally, the precipitate was washed with acetone, dried at room temperature, dissolved in water and freeze dried for 48 h in order to obtain a polysaccharide fraction, which will be furthered referred to as DMP (*Daphne Mezereum* Polysaccharide).

2.3. Fractionation of polysaccharides

The extraction and fractionation procedure used for obtaining the isolated polysaccharides is illustrated in Fig. 1. All fractions were filtered through 0.45 μm Millipore filters before they were applied to the columns.

2.3.1. Anion-exchange chromatography

A solution of DMP (5 mg/mL in dH₂O) was applied to a column packed with ANX SepharoseTM 4 Fast Flow (high sub) (GE Healthcare, 5 \times 25 cm). The column was eluted with degassed dH₂O (1 mL/min) to obtain a neutral fraction (DMP-NF), followed by a linear NaCl gradient (0–1.5 M, 2 mL/min) to give an acidic fraction (DMP-AF). The collection volume was 10 mL/tube. The carbohydrate elution profile was determined using the phenol-sulfuric acid method (DuBois, Gilles, Hamilton, Rebers, & Smith, 1956). The relevant fractions were pooled and dialyzed against dH₂O (cut-off 3500 Da), and freeze-dried for 48.

2.3.2. Size exclusion chromatography

DMP-NF (5 mg/mL in dH₂O) was applied to a Sephacryl S100 HR column (Pharmacia, 2×55 cm), eluted with degassed dH₂O (0.5 mL/min) and volumes of 1 mL/tube were collected. The carbohydrate elution profile was determined using the phenol-sulfuric acid method (DuBois et al., 1956). The relevant fractions were pooled and freezedried for 48 h. The size exclusion column chromatography experiment was performed using an Äkta FPLC system (Pharmacia Äkta, Amersham Pharmacia Biotech) with a fraction collector. The Unicorn 4.0 software (GE Healthcare) was used to set up and monitor experiments.

2.4. Enzymatic degradation by pectinase

DMP-AF (200 mg) was dissolved in minimal volume acetate buffer (50 mM, pH = 4) and added pectinase from Aspergillus niger (200 μ L, 55 U/mg, Sigma Aldrich). One unit of pectinase liberates 1 µmol of GalA from polygalacturonic acid per min at pH 4.0 at 25 °C. The solution was incubated at 25 $^\circ\text{C}$ for 24 h. Additional pectinase (20 $\mu\text{L})$ was added after 8 h. The solution was brought to boil in order to denature the enzyme, cooled down and applied to a HiLoad[™] 16/60 Superdex[™] 200 prep grade column (GE Healthcare, 16×60 cm). The column was eluted with degassed dH₂O at 0.5 mL/min and fractions were collected (2 mL/tube). Based on the phenol-sulfuric acid assay, the relevant fractions were pooled and freeze-dried for 48 h, and an enzymatically degraded product (DMP-ED) was obtained. The size exclusion column chromatography experiment was performed using an Äkta FPLC system (Pharmacia Akta, Amersham Pharmacia Biotech) with a fraction collector. The Unicorn 4.0 software (GE Healthcare) was used to set up and monitor experiments.

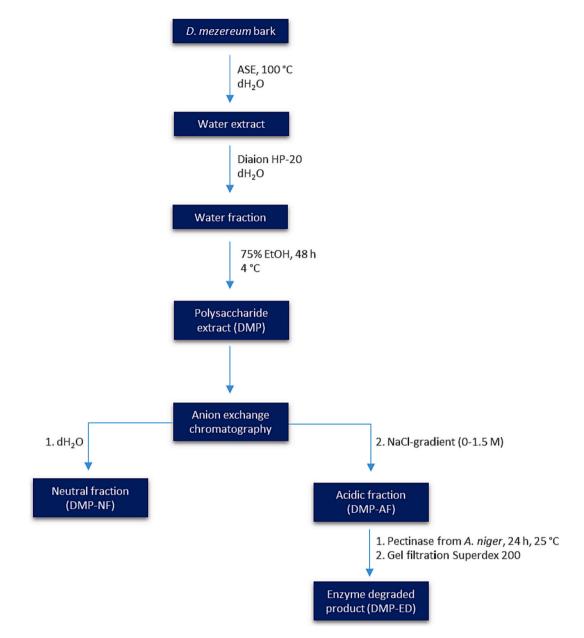

Fig. 1. Flowchart for extraction and fractionation of polysaccharides from the bark of D. mezereum.

2.5. Determination of monosaccharide composition

The monosaccharide composition was determined as previously described (Chambers & Clamp, 1971; Ulriksen et al., 2022). In short, the samples were subjected to 3 M HCl in anhydrous methanol for 24 h at 80 °C. Trimethylsilylated derivatives of the methyl glycosides obtained after methanolysis were analyzed using a Restek RTx-5 silica column (30 m, i.d. 0.25 mm, 0.25 μ m film thickness) coupled to a Focus GC (ThermoFisher Scientific, Waltham, MA) with a flame-ionization detection. The parameters used for the gas chromatography were identical to previous studies (Wold et al., 2018). Helium was used as a carrier gas and Chromeleon software v.6.80 (Dionex Corporation, Sunnyvale, CA) was used to analyze the results. Mannitol was used as an internal standard.

2.6. Linkage analysis

Glycosidic linkage analysis was performed as described earlier (Pettolino, Walsh, Fincher, & Bacic, 2012; Wold et al., 2018). All samples were subjected to carboxyl reduction prior to methylation. In short, the samples were reduced by NaBD₄, and methylated by NaOH in DMSO and methyl iodide. This was followed by hydrolysis by trifluoroacetic acid and a subsequent reduction by NaBD₄. Finally, acetylation was achieved by adding 1-methylimidazole and acetic anhydride. The partially methylated samples were analyzed by GCMS-QP2010 (Shimadzu Corporation) with a Restek Rxi-5MS silica column (30 m, i.d. 0.25 mm, 0.25 µm film thickness), split injection and set at a constant pressure mode. Initial flow was 1 mL/min. The injector and interface temperatures were 280 °C. At the time of injection, the column temperature was 80 °C. After 5 min, the temperature was increased with

10 °C/min up to 140 °C. This was later followed by increase of 4 °C/min to 210 °C and lastly 20 °C/min to 310 °C, where it was kept for 4 min. Helium was used as a carrier gas, and the temperature of the ion source was 200 °C. Spectra were analyzed using GC–MS solution software, v.2.10 (Shimadzu Corporation).

2.7. Precipitation with β -Yariv glucosyl reagent

The presence of arabinogalactan type-II was determined for DMP-NF, DMP-AsF and DMP-ED by precipitation with β -Yariv glucosyl reagent by single radial diffusion with arabic gum (1 mg/mL in dH₂O) as a positive control (van Holst & Clarke, 1985). In short, 3.5 mL of a solution containing 0.02% (*w*/*v*) sodium azide, 0.86% (*w*/*v*) sodium chloride and 1% (*w*/*v*) agarose in dH₂O was heated to boiling. β -Yariv glucosyl reagent (100 µL, 2 mg/mL) was added before the solution was poured onto a gel bond film (5 × 7 cm) and allowed to cool down. All samples were made in concentrations of 2 mg/mL and 4 mg/mL in dH₂O. Three wells were made for each concentration of each sample using a gel puncher. The wells were filled with either 2, 4 or 6 µL of each solution. The gel bond film was placed in a moist chamber overnight. A colored precipitate is formed with compounds containing AG-II structures.

2.8. Iodine-starch test

The presence of starch was determined for DMP-NF, DMP-AF and DMP-ED by adding a few drops of aqueous iodine-potassium-iodide solution to each fraction (Hunter, McIntyre, & McIlroy, 1970). Starch from potato (Sigma Aldrich) was used as a positive control and dH_2O as a negative control. A positive reaction gives a dark bluish color. The presence of starch was visually determined by comparing all of the solutions.

2.9. Determination of 3-deoxy-D-manno-2-octulosonic acid

The presence of 3-deoxy-D-manno-2-octulosonic acid (KDO) was determined for DMP-AF and DMP-ED with KDO as positive control as described previously (Karkhanis, Zeltner, Jackson, & Carlo, 1978). In short, each sample (100 µL, 0.1 mg/mL in dH₂O) was transferred to a pyrex tube, added dH_2O (150 $\mu L)$ and H_2SO_4 (250 $\mu L,$ 0.2 M), before being heated for 30 min at 100 °C. The solutions were cooled down, centrifuged (3000 rpm, 5 min) and 500 µL of the supernatant was transferred to a new pyrex tube followed by addition of HIO₄ (250 µL, 0.04 M in 62.5 mM H₂SO₄). The samples were incubated for 20 min. Each tube were added a fresh solution of Na₂SO₃ (500 µL, 2% in HCl), vortexed and incubated until the brown color disappeared. Then, a solution of thiobarbituric acid (500 μ L, pH = 3, 0.6% in dH₂O) was transferred to each tube and heated for 15 min at 100 °C. The samples were taken out and DMSO (1 mL) was immediately added to each solution. Finally, the samples were cooled down and the absorbance was measured at 548 nm using a Molecular Devices FlexStation 3 Reader.

2.10. Molecular weight determination

The average molecular weight (M_W) of each sample was determined as described earlier (Fu et al., 2022). In short, each fraction (2 mg/mL, 0.5 mL) was applied to a SuperoseTM 6 column (Amersham Biosciences, 1×30 cm) and eluted with NaCl (10 mM, 0.5 mL/min). The collection volume was 0.5 mL/tube. The M_W of all samples were calculated using a calibration curve where the logarithmic value of M_W of different dextran polymers (5.6, 80, 150, 233 and 475 kDa) was plotted against the fraction tube number.

2.11. Nuclear magnetic resonance (NMR) spectroscopy

Fractions (5–10 mg) were dissolved in D_2O (500 µL, 99.9%, Sigma) and sodium 2,2-dimethyl-2-silapentane-5-sulfonate (Sigma) was used as

the reference compound. All experiments were carried out on a Bruker Advance III HD 800 MHz spectrometer quipped with a 5-mm cryogenic CP-TCI z-gradient probe at 333.15 K (Bruker, Rheinstetten, Germany). The following spectra were recorded using TopSpin 3.5 with or without CW presaturation for suppression of water signals: ¹H NMR (continuouswave presaturation, pulse program "zgpr"), ¹³C NMR (pulse program "zrestse.dp.jcm800"), phase sensitive COSY (pulse program "cosygpprqf"), TOCSY (pulse program "dipsi2hpr", 80 ms mixing time), ROESY (pulse program "roesyph", mixing time 250 ms), NOESY (pulse program "awnoesygppr", 250 ms mixing time), HSQC (pulse program "awhsqcedetgpsisp2.3–135pr" and "awhsqc135pr") and HMBC (pulse program "awhmbcgplpndqfpr" and "awshmbcctetgp12nd.m"). Spectra were processed and analyzed using TopSpin 3.6.2 software (Bruker).

2.12. Determination of the degree of methylation and acetylation

The degree of methylation (DM) and acetylation (DAc) of the pectin in DMP-AF was determined by a quantitative ¹H NMR method described by Müller-Maatsch, Caligiani, Tedeschi, Elst, & Sforza, 2014. In short 10 mg of DMP-AF was incubated at 2 h in room temperature with 1 mL 0.4 M NaOH in D₂O. 4 µL of a 5%-solution of TSP in D₂O was added as internal standard. The supernatant was centrifuged, filtered through a 0.45 µm Millipore filter and transferred to an NMR tube. The ¹H NMR spectrum was recorded on a Bruker Advance III HD 800 MHz spectrometer equipped with a 5-mm cryogenic CP-TCI z-gradient probe (Bruker, Fällanden, Switzerland). The spectrum was acquired at 298 K using 90° pulse length. Sixty-four scans were acquired with a timedomain (TD) of 81,088, a spectral width (SW) of 16,025.64 Hz, an acquisition time (AQ) of 2.53 s, and a relaxation delay (D1) of 5 s. The experiment was carried out without water suppression. The spectrum was processed and analyzed using TopSpin 3.6.2 software (Bruker). The spectrum was phased, baseline corrected, and referenced to the TSP peak (0 ppm). The SI-value was 65,536 (zero filling performed), WDW = EM, the line broadening (LB) value was 0.30 Hz. Pulsecal was used to optimize P1. A manual integration of the methanol and acetic acid signals (3.354 ppm for methanol and 1.919 ppm for acetic acid) and comparison with the TSP area was performed in order to quantitatively determine the content of methanol and acetic acid in DMP-AF. The integrals were converted into mass values (mg) according to the formula in Müller-Maatsch et al., 2014. Further, the degree of methylation and acetylation was calculated, using the following equation:

degree of methylation = $\frac{mol \ of \ methanol}{mol \ of \ galacturonic \ acid} \times 100\%$

2.13. Enzyme-linked immunosorbent assay (ELISA)

Human TNF- α or human IFN- γ ELISA were tested using a kit from Mabtech (Sweden) as described previously (Ulriksen et al., 2022). PBMCs (1 \times 10⁵ cells/200 µL) were co-cultured in complete medium (RPMI-1640 (ThermoFisher Scientific) supplemented with 10% heatinactivated fetal bovine serum (Atlanta Biologics), 1 mM Sodium pyruvate, 50 μ M 2-Mercaptoethanol and 1 \times Penicillin/Streptomycin (ThermoFisher Scientific)) in presence of 1000 µg/mL, 100 µg/mL, 10 μ g/mL or 1 μ g/mL of each sample in 96-well U-bottom plates. Medium alone served as negative control, and 1 μ g/mL of Concavilin A (ConA) as positive control. 96-well EIA/RIA Flat Bottom High Binding Plates (Corning) were coated overnight (4 °C) with capture antibodies in PBS. The following day, plates were blocked for 1 h at RT with 200 μ L/mL Incubation buffer (PBS with 0.05% Tween-20 and 0.1% BSA). After incubation, the plates were washed and assay standards and supernatans were added to each well and incubated for 2 h at RT. Following incubation, the plates were washed and human TNF- α monoclonal detection antibody (Mabtech) diluted in incubation buffer (1 µg/mL) were added to each well (100 µL/well) before incubating for 1 h. After washing, streptavidin-HRP (Mabtech) was added and plates were incubated for 1

h. After incubation and washing, the plates were developed with TMB substrate for 15 min, and development was stopped by adding 1 M HCl. All washes were done using a BioTek ELx405 plate washer with 0.05% Tween-20 in PBS. Absorbance at 450 nm was measured using a Molecular Devices FlexStation 3 Reader. Data were calculated based on standard curve and presented as concentration of pg/mL cytokines in test samples. All samples were run in duplicates on the same plate and all runs were repeated three times.

3. Results and discussion

3.1. Isolation and purification of polysaccharide fractions

The Daphne mezereum polysaccharide fraction (DMP) was obtained after ethanol precipitation of the bark water extract. This resulted in a 3.1% yield (related to dried, pulverized plant material) of a brown precipitate. As illustrated by Fig. 1 and the elution profiles in Fig. 2, two fractions were further isolated after applying DMP to an anion exchange column. A neutral fraction, DMP-NF (Fig. 2A), was obtained after eluting with water and an acidic fraction, DMP-AF (Fig. 2B), after eluting with a NaCl-gradient. Both DMP-NF and DMP-AF were white precipitates with a yield of 3.3% and 49% (related to DMP), respectively. DMP-AF was further treated with pectinase due to GalA being the predominant monosaccharide (Table 1). The enzyme solution was purified by gelfiltration on a Superdex 200 column and led to the isolation of an enzymatically degraded product DMP-ED (Fig. 2C) as a white precipitate with a yield of 2.5% (related to DMP-AF). The relevant fractions that were pooled for each DMP-fraction are between the two vertical lines in Fig. 2A-2C.

Table 1

Monosaccharide	composition	(mol%)	after	methanolysis	and	GC-analysis of	f
polysaccharide c	ontaining frac	ctions fro	om D.	mezereum.			

Monosaccharide	DMP	DMP-NF	DMP-AF	DMP-ED
Arabinose (Ara)	6.6	24	2.2	8.2

Galacturonic acid (GalA)	54	7.9	85	36
Total carbohydrate content (%w/w)	66	90	82	97

3.2. Molecular weight determination of polysaccharide fractions

Dextran polymers with increasing weight average molecular weights (M_W) were applied to a Superose 6 column in order to make a calibration curve to estimate the M_W of DMP-NF, DMP-AF and DMP-ED. The logarithmic value of the dextran polymers were plotted against the fraction tubes in which they were collected. As illustrated by Fig. 2E, DMP-AF had the highest M_W , followed by DMP-NF, which were calculated to be 484 and 24.5 kDa, respectively. Treating DMP-AF with pectinase (DMP-ED) resulted in a fraction with a M_W of 40.3 kDa, which was expected due to the significant amounts of GalA being released from DMP-AF (Table 1).

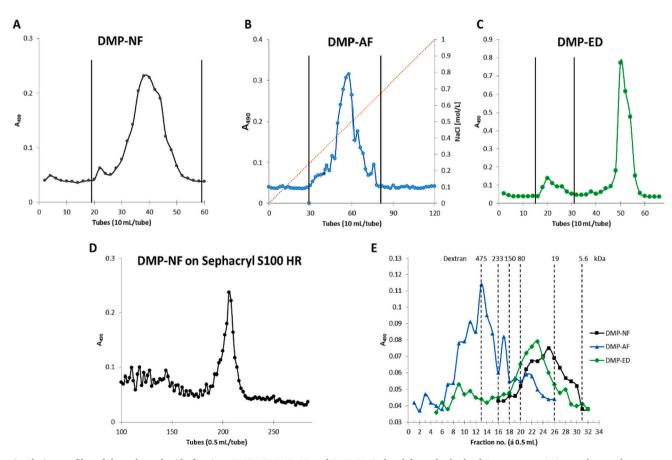

Fig. 2. Elution profiles of the polysaccharide fractions DMP-NF, DMP-AF and DMP-ED isolated from the bark of *D. mezereum*. Anion exchange chromatography elution profiles of DMP-NF (A) and DMP-AF (B) on ANX Sepharose; Size exclusion chromatography elution profiles of DMP-ED (C) on Superdex 200, of DMP-NF on Sepharcryl S100 HR (D) and of DMP-NF, DMP-AF and DMP-ED on Superose 6.

3.3. Monosaccharide composition of isolated polysaccharide fractions

The monosaccharide compositions of DMP, DMP-NF, DMP-AF and DMP-ED are given in Table 1. The GC-chromatograms are shown in Fig. S1. In the DMP-fraction, GalA is the most abundant monomer. In addition, noticeable amounts of Ara, Gal and glucose (Glc) were also observed, which could be an early indication of the presence of pectic polymers, hemicellulose and starch. DMP-NF consisted of significant amounts of Ara, Glc and Gal, in addition to xylose (Xyl) and mannose (Man), which could derive from different types of polysaccharides, such as arabinans, arabinogalactans (AG), hemicellulose and starch. Interestingly, minor amounts of GlcA and GalA were also observed in DMP-NF, which could be due to methyl- or acetyl-esterification of the uronic acids, co-eluting with the neutral fractions.

The isolation of DMP-AF yielded a polysaccharide containing relatively high amounts of GalA (85%). Ara, Rha, Gal and Glc were also observable in smaller amounts. This could indicate a pectic polysaccharide with a large HG-domain.

After enzymatically cleaving off GalA in DMP-AF with pectinase, a relative increase of all other monosaccharides in DMP-ED (Table 1) was observed, compared to DMP-AF. In specific, the content of Rha increased significantly, which is probably due to Rha being a part of the backbone in RG-I region of pectins. Ara and Gal were also observed in significant amounts, which could derive from side chains such as arabinans and galactans, or AGs.

3.4. Structural characterization of isolated polysaccharide fractions

3.4.1. Glycosidic linkages

The isolated polysaccharide fractions were analyzed by GC–MS after carboxyl reduction and per-methylation in order to investigate the glycosidic linkages of the monomers. The results are presented in Table 2.

Ara, Glc and Gal were the main monomers detected in DMP-NF. Regarding Ara, the major linkage type observed was 1,5-Araf, in addition to T-, 1,2,5- and 1,3,5-Ara linked units. This suggests a backbone consisting of 1,5-Araf units, with branching occurring at C2 and C3, and could indicate the presence of an arabinan (Mandal et al., 2011). Earlier studies have reported T-Araf, 1,2- and 1,3-Araf residues as possible side chains of arabinans (Xia, Liang, Yang, Wang, & Kuang, 2015). The amount of T-Araf compared to 1,2- and 1,3-Araf insinuate that most of the side chains are mainly monomers of T-Araf.

The main linkage pattern for Glc was 1,4-Glc*p*, which could indicate that DMP-NF contained either starch or hemicellulose. The main difference between the aforementioned polysaccharides is the anomeric configuration. An iodine-starch test can easily distinguish between starch and hemicellulose. Adding a few drops of iodine-solution to DMP-NF and dH₂O (negative control) resulted in a yellow solution, thus asserting the presence of hemicellulose.

Based on the observation above and the linkages observed for mannose and xylose, possible hemicelluloses that may be present are mannans, xylans and xyloglucans. The presence of 1,4- and 1,4,6-Manp may derive from mannans which consist of a linear backbone composed entirely of β -1,4-linked Manp with branching occurring at O-6. They can be furthered be divided into galactomannan (substituted by single Galp units), glucomannan (backbone consisting of both β -1,4-linked Manp and β -1,4-linked Glcp) and galactoglucomannan (glucomannan backbone terminated with single Galp units at O-6) (Ebringerová, Hromádková, & Heinze, 2005). Xylans are composed of β -1,4-linked Xylp, and depending on the side chain, can further be divided into glucoronoxylans (GlcpA attached to O-2), arabinoxylans (Araf attached to O-2 or/and O-3) or arabinoglucoronxylans (monosubstituted at O-2 and O-3 with GlcpA and Araf, respectively) (Ebringerová et al., 2005).

The Gal units were found to be present as 1,4- and 1,3,4-Galp and 1,3-, 1,6-, 1,3,6- and 1,3,4,6-Galp, suggesting that DMP-NF contains both arabinogalactan type-I (AG-I) and type-II (AG-II), respectively. The

Note: Trace = <0.5 mol%, n.d. = not detected.

presence of the latter was confirmed by the Yariv test. Both AG-domains consist of a Gal-backbone. However, in AG-I the backbone is made up of β -1,4-Galp with branching occurring at O-3, usually with T-Araf, or sometimes even T-Gal. AG-II on the other hand consist of a backbone of β -1,3-Galp with branching occurring at O-6 with β -1,3-Galp or β -1,6-Galp units. The side chains can again be terminated with T-Araf or T-GlcpA (Yamada & Kiyohara, 2007).

In an attempt to separate these polysaccharides, DMP-NF was applied to a Sephacryl S-100 column. As seen by Fig. 2D, the separation was not successful. Applying the sample to the Superose 6 column did also not separate them (Fig. 2E). Based on the above, DMP-NF might consist of a mixture of arabinans, arabinogalactans and hemicelluloses with similar M_W . The different parts may also be covalently linked.

The dominant linkage type in DMP-AF was 1,4-linked GalA, as expected for a pectin. However, it accounted for 80% of all linkage types, which is a substantial amount given the fact that 1,4-GalA usually make up around 65% of pectins (Mohnen, 2008). In addition, minor amounts of 1,2,4-linked GalA and traces of 1,3,4-linked GalA were also observed, suggesting a low degree of branching at C-2 or C-3. The remaining monomers were only detected as minor amounts or traces. Presence of T-Xylp may indicate a xylogalacturonan region, in which frequent single Xylp-residues are β -1,3-linked to the Gal-A units (Mort, Zheng, Qiu, Nimtz, & Bell-Eunice, 2008). T-Fucp may also be substituted at C-3 in the HG-region (Fu et al., 2022).

By enzymatically cleaving off the α -1,4-GalA units in DMP-AF by a pectinase, several linkage types were revealed in higher amounts, making it possible to further elucidate the structure of the RG-I region. As for DMP-AF, DMP-ED also contained 1,4- linked GalpA units. In addition 1,2-Rhap and 1,2,4-Rhap linkages were found, most probably deriving from a RG-I region of the pectin. In addition to arabinan- and AG-II type linkages, 1,4- and 1,3,4-Galp also suggests presence of arabinogalactan-I (AG-I). The 1,4-Galp could also be a part of a linear galactan side chain. The branches may be terminated by T-Araf or arabinans (Mohnen, 2008).

In order to determine the possible presence of RG-II in DMP-ED, a method to determine the amount of 3-deoxy-D-manno-2-octulosonic acid (KDO) was applied (Karkhanis et al., 1978). Both DMP-AF and DMP-ED were subjected to this experiment, in addition to KDO and water as positive and negative control, respectively. Both DMP-AF and DMP-ED tested positive for KDO, thus indicating that both fractions may consist of a RG-II region. This could explain the presence of 1,2,4- and 1,3,4-GalpA, as branching in this region occurs in either O2 or O3, in addition to the presence of T-Rhap, 1,3-Rhap, 1,2,3-Fuc and T-GalpA (O'Neill, Ishii, Albersheim, & Darvill, 2004). However, further studies should be performed in order to confirm the presence of the RG-II region.

3.4.2. NMR analysis

DMP-NF, DMP-AF and DMP-ED were analyzed by NMR in order to further elucidate their structures. The data were interpreted by comparing and matching chemical shift values from the 1D-spectra ¹H (Fig. S2A, S3A and S4A) and ¹³C (Fig. S2B, S3B and S4B) and the 2D-spectra COSY (Fig. S2C, S3C and S4C), NOESY (Fig. S3D), ROESY (Fig. S2D and S4D), TOCSY (Fig. S2E, S3E and S4E), HSQC (Fig. 3) and HMBC (Fig. 3, Fig. S2F and Fig. S3F). The shift values were assigned to the linkage patterns observed by GC–MS and compared with earlier reported data. The results are presented in Table 3.

The anomeric region in a ¹H NMR spectra is defined as peaks occurring in the range between δ 5.6–4.4 (Speciale et al., 2022). It should be noted that some non-anomeric protons can also appear in this region, especially in the upfield part of the region (Yao, Wang, Yin, Nie, & Xie, 2021). Furthermore, the CH₃-group in Rha occur usually in δ 1.1–1.4 in ¹H NMR and δ 16–18 region in ¹³C NMR. Peaks related to acetyl- and methyl groups are encountered in δ 2.0–2.2 and 18–22 and δ 3.3–3.8 and 55–61, respectively (Yao et al., 2021).

3.4.2.1. NMR analysis of DMP-NF. Several peaks and cross peaks were observed around δ 110 in the HSQC spectrum of DMP-NF (Fig. 3A), which can be assigned to the anomeric carbons in the Araf-residues observed in the methylation analysis. For instance, the intense signals at δ 5.15/109.9 (TA₁-1), δ 5.19/110.0 (TA₂-1) and δ 5.26/112.0 (TA₃-1) observed in the HSQC spectra can be assigned to the anomeric carbon of α -Araf-(\rightarrow 1. The α -Araf residues may differ in terms of their appendences to substituted L-Araf (at O-2, O-3 or O-5) and D-Galp (at O-3 or O-6), hence giving rise to the different proton/carbon signals (H. Zhang et al., 2020). Due to overlapping signals between the H-1 of T-Araf and H-2, H-3 and H-5 of substituted Araf or H-3, H-4 and H-6 of substituted Galp, it was not possible to distinguish between the TA-residues. HMBC (Fig. S2F) revealed cross peaks for H-1 of TA₁ δ 5.15/83.4 (H1/C2-TA₁), 5.15/79.5 (H1/C3-TA1) and 5.15/86.9 (H1/C4-TA1) which were assigned to C-2, C-3 and C-4, respectively. Furthermore, H-1 correlated to protons at δ 5.15/3.74 and δ 5.15/3.84 in ROESY (Fig. S2C). The shifts were assigned to the H-5 protons due to the downfield shift of the carbon that the protons are attached to (TA₁-5) (Wefers & Bunzel, 2016). The shifts for the remaining TA-residues were also assigned in similar manner.

The H/C correlation at δ 5.09/110.4 (A_{1,5}-1) in HSQC (Fig. 3A) can be assigned to the C-1 in \rightarrow 5)- α -Araf-(1 \rightarrow . COSY (Fig. S2C) revealed that a cross peak for the anomeric proton at δ 5.09/4.13, which can be appointed to the H-2 (A_{1,5}-2). Furthermore, the HMBC spectrum (Fig. S2F) showed cross peaks at δ 5.09/79.5 (A_{1,5}-3) and 5.09/85.2 (A_{1,5}-4), which can be assigned to C-3 and C-4, respectively. H-5 was deduced by HMBC-correlations (Fig. 3A) at δ 3.89/110.4 (A_{1,5}-5). Similar approach was also applied when assigning chemical shifts to the branched arabinans (1,2,5- and 1,3,5-Araf). The shifts were in accordance with earlier reported values (Shakhmatov, Makarova, & Belyy, 2019).

Signals correlating to AG-II linkages were also observed. More specifically, H/C correlations at δ 4.63/107.2 (G_{1,3}–1), δ 4.53/105.8 (G_{1,3,6}–1) and δ 4.48/106.7 (G_{1,3,4,6}–1) in HSQC (Fig. 3A) were assigned to the anomeric carbons of \rightarrow 3)- β -Galp-(1 \rightarrow , \rightarrow 3,6)- β -Galp-(1 \rightarrow) and \rightarrow 3,4,6)- β -Galp-(1 \rightarrow , respectively. COSY (Fig. S2C) was used to assign the shift of the H-2 proton and the remaining shifts were assigned using ROESY (Fig. S2D) and TOCSY (Fig. S2E). The assigned shifts were in accordance with earlier reported values (Fu et al., 2022; H. Zhang et al., 2020). COSY (Fig. S2C) also revealed a strong proton-proton coupling at δ 4.63/3.35, which could indicate two overlapping anomeric protons. This was also further confirmed by HMBC cross peak (Fig. 3A) at δ 3.35/105.8 (H2/C1-G*_{1,4}). Given the upfield shift and the intensity of this coupling, the spin system δ 3.35/76.0 (G*_{1,4}–2) was assigned to the H-2 of \rightarrow 4)- β -Glcp-(1 \rightarrow residue. ROESY correlations (Fig. S2D) for H-2 at δ 3.35/3.50, 3.35/3.65 and 3.35/3.89 were

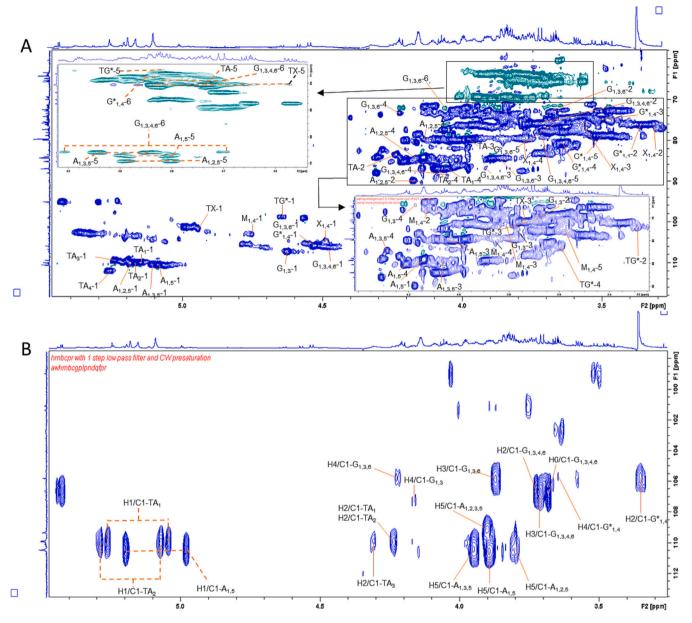

Fig. 3. 2D-NMR with assigned H/C-correlations of DMP-fractions isolated from the bark of *D. mezereum*. HSQC (A) and HMBC (B) spectra of DMP-NF; HSQC (C) and HMBC (D) spectra of DMP-AF and HSQC (E) and HMBC (F) spectra of DMP-ED. Positive signals (blue) are either methine (CH) or methyl (CH₃), while negative signals (green) are methylene (CH₂) groups.

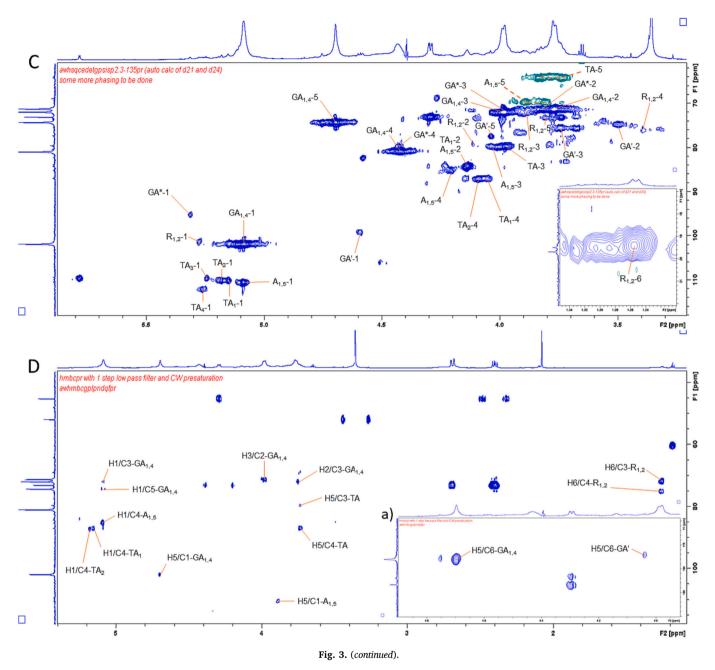

appointed to H-3, H-4 and H-6, respectively. Ultimately, H-5 was deduced by the H-5/C-2 correlation at δ 3.52/76.0 in HMBC (Fig. S2F). This also asserts the results obtained from the iodine-starch test discussed earlier. The shifts belonging to (4 $\rightarrow\beta$ -Glcp were also determined in similar fashion. The results were in good agreement with published values (Ding et al., 2016; Y. Guo et al., 2023; Makarova & Shakhmatov, 2021).

The presence of \rightarrow 4)- β -Manp-(1 \rightarrow (**M**_{1,4}) could also be observed by signals at δ 4.76/103.1 (**M**_{1,4}-1) in HSQC (Fig. 3A). The ROESY spectrum (Fig. S2D) revealed cross peaks for H1 at δ 4.76/4.12, 4.76/3.82, 4.75/3.85 and 4.76/3.56, which were assigned to H-2-H-5, respectively. This might suggest the presence of mannans. Moreover, ROESY (Fig. S2D) also revealed *trans*-glycosidic correlation between H-1 of **M**_{1,4} and H-4 of **G***_{1,4} at δ 4.76/3.65, and between H-1 of **G***_{1,4} and H-4 of **M**_{1,4} at δ 4.53/3.56. This might indicate the presence of the repeating disaccharide unit \rightarrow 4)- β -Manp-(1 \rightarrow 4)- β -Glcp-(1 \rightarrow found in

glucomannans (Makarova & Shakhmatov, 2021).

Both α -Xylp-(1 \rightarrow (TX) and \rightarrow 4)- β -Xylp-(1 \rightarrow (X_{1,4}) could also be confirmed by the anomeric spin systems at δ 4.95/101.6 (TX-1) and δ 4.49/104.5 (X_{1,4}-1), respectively. The shift for the H-2 proton was assigned using COSY (Fig. S2C). The remaining protons were deduced by correlations in ROESY (Fig. S2D) and TOCSY (Fig. S2E). The presence of these Xylp residues might indicate that DMP-NF also contains xyloglucan and xylans. The results were in accordance with earlier reported values (Ding et al., 2016; Makarova & Shakhmatov, 2021).

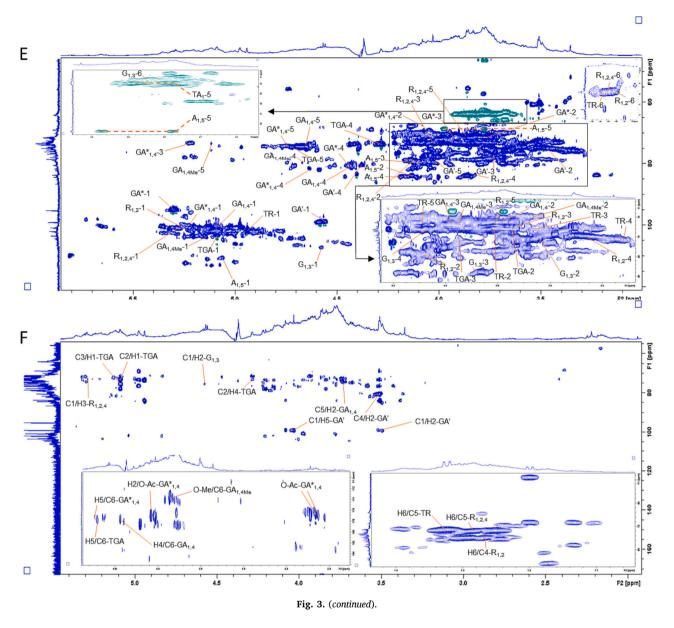

3.4.2.2. NMR analysis of DMP-AF. The spectra of DMP-AF were less crowded compared to the other fractions due to DMP-AF mainly consisting of GalpA (85%). The ¹H NMR spectra (Fig. S3A) consisted of four intense peak, one less than expected. With the help of the 2D-spectra, it was deduced that the missing signal overlapped with the water signal, and thus suppressed during acquisition of the one dimensional

spectrum. The H/C-correlation for the intense signal were observed at δ 5.09/101.8 (GA_{1,4}-1), 3.77/71.2 (GA_{1,4}-2), 3.98/71.9 (GA_{1,4}-3), 4.42/ 81.0 (GA_{1,4}-4) and 4.70/74.3 (GA_{1,4}-5) in HSQC (Fig. 3C), which can be assigned to H1/C1-H5/C5 in α -1,4-GalpA in the HG-domain, respectively. The remaining C-6 was deduced by the correlation at δ 4.70/178.0 (H5/C6-GA_{1,4}) in HMBC (Fig. 3D) (Shakhmatov et al., 2019). The presence of \Rightarrow 4)-GalpA residues (GA* and GA') were also confirmed. Cross peaks in COSY (Fig. S2C) and TOCSY (Fig. S2E) were used to assign several shifts (e.g. coupling between H-1 and H-2) and C-6 was determined based on HMBC correlations (Fig. 3D). The values were

in good agreement with earlier reported values (Fu et al., 2022). Due to low amounts of the other monosaccharide residues in DMP-AF, the assignment of remaining linkages was significantly more difficult. Nevertheless, the anomeric spin system δ 5.28/101.3 (**R**_{1,2}–1) was assigned to α -1,2-Rhap (**R**_{1,2}) and H-2 was assigned based on the protonproton coupling observed in COSY (Fig. S3C). The spin system at δ 1.26/ 19.5 in HSQC (Fig. 3C) was appointed to the C-6 of **R**_{1,2} due to its upfield shift. Protons coupling to H-6 at δ 1.26/3.39 and 1.26/3.81 in TOCSY (Fig. S3D) were appointed to H-4 and H-5, respectively. Ultimately, the HMBC spectrum (Fig. 3D) revealed a correlation at δ 1.26/71.8, which was assigned to the remaining C-3. The values were in accordance with reported values from earlier studies (Patova et al., 2019).

3.4.2.3. NMR analysis of DMP-ED. The NMR-spectra of DMP-ED on the other hand was significantly more complicated compared to DMP-AF. In similar manner as discussed above, shifts for the aforementioned linkages were deduced. Furthermore, 1,2,4- α -Rhap was identified by the anomeric spin system at δ 5.28/100.9 ($\mathbf{R}_{1,2,4}$ -1). Cross peaks for H-1 at δ 5.28/4.13, 5.28/4.03 and 5.28/3.82 in the ROESY spectrum (Fig. S4D) were allocated to H-2-H-4, respectively. The proton coupling to H-2 at δ 4.12/3.87 in TOCSY (Fig. S4E) was assigned to H-5 and the remaining H-6 was deduced by a strong correlation to C-5 at δ 1.28/71.4 (H6/C5- $\mathbf{R}_{1,2,4}$) in HMBC (Fig. 3F). The results were in good agreement with earlier reported values (Shakhmatov et al., 2019). In addition, the ROESY spectrum also showed correlation between the H-1 of $\mathbf{R}_{1,2}$ and H-5 of GA_{1,4}; H-1 of $\mathbf{R}_{1,2}$ and H-4 of GA_{1,4}, and H-2 of $\mathbf{R}_{1,2}$ and H-1 of

GA_{1,4}. This confirms the presence of the RG-I backbone moiety \rightarrow 4)- α -GalpA-(1 \rightarrow 2)-Rhap-(1 \rightarrow (Shakhmatov, Belyy, & Makarova, 2018).

In addition to α -1,4-GalpA, cross peaks in the downfield region of the HMBC spectrum suggested the presence of acetylated (GA*_{1,4}) GalpA. The \rightarrow 4)- α -3-O-Ac-GalpA-(1 \rightarrow residue was identified by cross peaks at δ 5.23/100.0 (GA*_{1,4}-1) in HSQC (Fig. 3E), δ 2.15/176.7 (O-Ac-GA*_{1,4}), 2.16/176.7 (O-Ac-GA*_{1,4}), 4.08/176.7 (H2/O-Ac-GA*_{1,4}) and 4.74/ 177.2 (H5/C6-GA*_{1,4}) in HMBC (Fig. 3F), and δ 2.15/5.22, 2.16/5.22 and 4.64/5.23 in ROESY (Fig. S4D). The correlation at δ 5.15/103.3, 5.12/73.3 and 3.86/55.4 in HSQC (Fig. 3E) and δ 3.86/173.8 in HMBC (Fig. 3F), in addition to δ 5.15/3.63 in COSY (Fig. S4C) and, δ 3.95/5.15 and 3.95/4.67 in ROESY (Fig. S4D), indicated that some of the α -1,4-GalpA was also methyl-esterified (Patova et al., 2019; Patova et al., 2021).

Based on the NMR-spectra presented in this study, it appears that DMP-NF is composed of a mixture of arabinans, AG-II, xyloglucans, xylans and mannans, while DMP-AF consisted of a pectic polysaccharide with an unusually long HG-backbone. After cleaving of the HGbackbone with pectinase, DMP-ED revealed a RG-I backbone with arabinan, galactan and AGs as side chains. However, due to weak correlations in NMR, it was not possible to determine how the side chains were connected to the RG-I backbone. To our knowledge, this study is the first to isolate and study the structure of the polysaccharides from the Daphne genus.

3.4.3. Degree of methylation (DM) and acetylation (DAc)

An important structural characteristic of homogalacturonan regions in pectin is esterification of the GalA residues with methanol and/or acetic acid. The DM corresponds to the percentage of carboxyl groups that are esterified with methanol, while the degree of acetylation (DAc) is the percentage of GalA units being esterified with one acetyl group (Voragen, Thibault, Axelos, Renard, & Pilnik, 1995). To determine the DM and DAc of the homogalacturonan in DMP-AF an ¹H NMR method was performed as described by Müller-Maatsch et al., 2014. The ¹H NMR spectrum of DMP-AF is shown in Fig. 4. The DM and DAc of the GalA residues were calculated based on the content of methanol and acetic acid, and the content of GalA. The content of GalA (mol%) was determined by methanolysis, followed by GC. Based on the calculations it was shown that the DM and DAc in DMP-AF was 22.9%, and 1.8%, respectively. This is in accordance with the literature where methylesterification is regarded to be common for pectins, while acetylesterification is usually low (Levigne, Thomas, Ralet, Quemener, & Thibault, 2002). Further, pectins are usually classified as low DM pectins (DM < 50%) or high DM pectins (DM > 50%), and based on this DMP-AF

Table 3

NMR chemical shift assignment of DMP-NF, DMP-AF and DMP-ED. The spectra were recorded at 60 °C in D₂O.

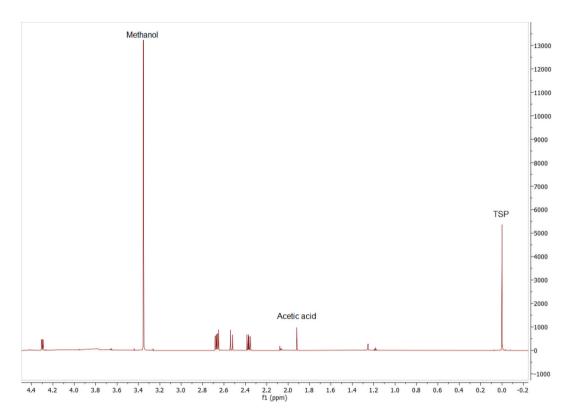

Fig. 4. ¹H NMR spectrum of DMP-AF. The signals of methanol and acetic acid are found at 3.354 ppm and 1.919 ppm, respectively. TSP is used as internal standard.

is considered a low DM pectin (Beukema, Faas, & de Vos, 2020).

3.4.4. Immune-activating effects of DMP-fractions

To assess the immune activating effect of the DMP-fractions, secretions of TNF- α and IFN- γ from PBMCs were analyzed. Previous studies indicates that pectic arabinogalactans can activate immune cells by recognizing and binding to specific PRRs, such as TLR4, TLR2 and CD-19 (Nergard et al., 2005). This can then lead to the transcriptional activation and production of inflammation-related cytokines (Yin, Zhang, & Li, 2019). The receptors may work separately or cooperate with other receptors by forming clusters of signaling complexes.

As illustrated in Fig. 5, DMP-AF exhibited significantly lower effect in inducing cytokine secretion from PBMCs compared to the other DMP-fractions. Given the fact that the HG-domain is a substantial part of DMP-AF, the lower bioactivity observed may be due to the presence of uncommonly high amounts of GalA residues (85%). By enzymatically cleaving of the 1,4-linked GalA in DMP-AF, DMP-ED was isolated and a significant increase in cytokine secretion was observed. Based on previous studies, there may be several possibilities which could explain the difference in bioactivity. For instance, a previous study looking at how

the content of GalA in pectins affect immunomodulatory activity, reported a decrease in macrophage activity of pectins containing GalA residues >80% (Popov & Ovodov, 2013). These results could suggest a possible relationship between the GalA content in pectins and macrophage activity. Further, the DM of pectins is thought to influence their immune activating effects, but so far there is no clear evidence whether low or high DM is most active (Beukema et al., 2020). DMP-AF was found to be a low DM pectin.

A further possible explanation might be that the RG-I region becomes more sterically accessible to interact with PRRs on immune cells. Studies on pectic polysaccharide with a RG-I enriched domain, have reported promising immunostimulatory effects on PBMCs (McKay et al., 2021; Santos et al., 2021). The RG-I region consist of neutral side chains consisting mainly of Ara and Gal. Removal of these side chains have shown to significantly reduce the bioactivity in previous studies (do Nascimento, Winnischofer, Ramirez, Iacomini, & Cordeiro, 2017; Ho et al., 2015), thus indicating that they might play an important role for the bioactivity observed.

DMP-NF exhibited similar levels of cytokine secretion as DMP-ED at the highest concentrations. Due to the high amounts of Ara and Gal

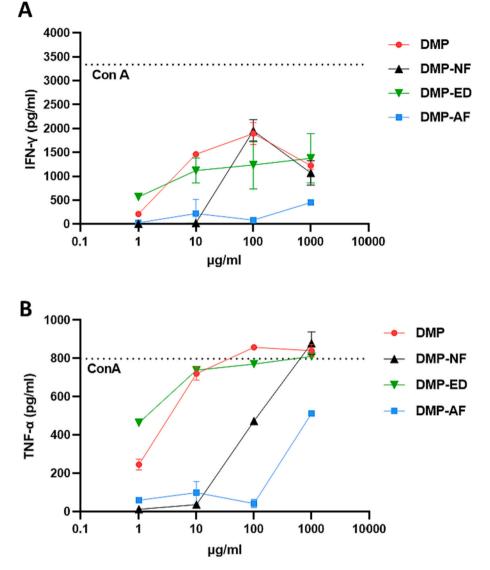

Fig. 5. IFN- γ (A) and TNF- α (B) secretion in supernatants from overnight cultures of PBMCs with DMP-fractions measured via ELISA. Data are presented as pg/mL and calculated based on a standard curve.

observed, it is likely that polysaccharides containing the aforementioned monosaccharides play a role in the bioactivity exhibited by the fractions. However, Glc was also observed in significant amounts (mainly β -1,4linked), suggesting the presence of hemicellulose. Previous studies have shown that hemicellulose, such as acetylated glucomannan and xyloglucans, can possess immunomodulating activity (Guo et al., 2022; Košťálová, Hromádková, Paulsen Berit, & Ebringerová, 2014). Another explanation may also be a synergistic effect of the different polysaccharides found in DMP-NF. Nevertheless, further isolation is required in order to determine this. Furthermore, a more comprehensive structure-bioactivity relationship study should be performed on the polysaccharide fractions in order to get a better understanding of what part of the polysaccharide fractions is responsible for the promising proinflammatory activity.

4. Conclusion

The present study is the first to report a comprehensive structural characterization of the polysaccharides in the Daphne genus. From a water extract of the bark of *D. mezereum*, a neutral fraction (DMP-NF) and an acidic fraction (DMP-AF) were isolated. The latter was further enzymatically degraded with pectinase, which led to the sub-fraction

DMP-ED. DMP-NF appeared to be a mixture of several polysaccharides such as arabinans, xyloglucans, xylans and mannans. The combination of GalA, Rha and Gal in DMP-AF suggests the presence of a pectic polysaccharide. The significant amounts of GalA, the α -1,4-linked GalpA in particular, points to a predominant HG-domain. DMP-ED contained a more isolated RG-I backbone with arabinan, galactan and arabinogalactan as side chains. The levels of TNF- α and IFN- γ secreted by PBMCs after stimulation with DMP-NF and DMP-ED indicated potent immuneactivating properties of these two fractions, that were significantly higher than that of DMP-AF. Aspects such as GalA-content, molecular weight and steric accessibility of RG-I backbone may be some of the reasons for the difference observed in the bioactivity. This study does not only show the diversity of polysaccharide that may be found in *D. mezereum*, but also their potential as immunomodulators.
