Anisotropic carrier and exciton confinement in T-shaped quantum wires revealed by magneto-photoluminescence

W. Langbein, H. Gislason, J.M. Hvam, J. Zeman* Mikroelektronik Centret, The Technical University of Denmark, Building 345 east, DK-2800 Lyngby, Denmark; E-mail: langbein@mic.dtu.dk

The realization of one-dimensional (1D) semiconductor nanostructures with large confinement energies is of importance for device applications. Different techniques such as growth on tilted substrates (Serpentine superlattices) or prepatterned substrates (V-groove quantum wires) and the cleaved-edge overgrowth of T-shaped quantum wires (T-QWR) have been demonstrated. For the T-shaped structures, the confinement energy has been recently increased to above 2kT at room temperature by optimizing structure parameters. A decreased exciton diameter in the [110] direction in the wire compared with the [001] well was revealed by magneto-photoluminescence. We determine here the extension of the T-shaped quantum wire (T-QWR) state in both confining directions [110] and [001] to verify its 1D character, as shown for crescent-shaped wires.

To quantitatively analyze the data, we apply a free particle model in the conduction and valence band state, respectively. A quantitative agreement is found.

QWA4 Fig. 2. (a) Calculated QWR states in the T-QWR structure. The structure shape is shown on the left; the contours of constant probability are plotted in the middle and right graphs for the conduction and valence band state, respectively. (b) Calculated probability distributions of the conduction band state averaged along the [001] and [110] direction, respectively. The bars give the measured extensions $w_{FWHM}^{[001]}$, $w_{FWHM}^{[110]}$.

QWA4 Fig. 1. (a) QWR PL spectra for magnetic fields from 0 to 24 T in the [001] direction. The QWR and the [001] QW transitions are visible. (b) Energy shift of the QWR PL as a function of the field strength for field directions as labeled.

The investigated optimized T-QWR sample with 37 meV confinement energy consists of a 18-nm [001] $\text{Al}_{0.95}\text{Ga}_{0.05}\text{As}$ multiple quantum well (QW) structure intersecting with a 4.3-nm [110] GaAs QW, within $\text{Al}_{0.3}\text{Ga}_{0.7}\text{As}$ barriers. It was excited by an Ar$^+$ laser at 514 nm using a multimode fiber. The photoluminescence (PL) at temperatures between 5 K and 30 K was collected by the fiber, dispersed in a monochromator, and detected by a gallium arsenide (GaAs) photomultiplier. A magnetic field from 0 to 26 T was applied by a superconducting and a resistive magnet.

In Fig. 2a, the calculated confined electron and hole squared wave functions for the QWR$^3$ are shown, localized at the intersection. Taking these results, the calculated probability distributions along the two quantization directions [001] and [110] are compared with the deduced FWHM of the electron wave functions in Fig. 2b. A qualitative agreement is found.

In Ref. 3, we can deduce the three exciton Bohr radii $a_{[001]}$, $a_{[110]}$, and $a_{[100]}$ and the exciton binding energy $E_x$ using the diamagnetic shifts (see Table 1). The result shows an anisotropic exciton wave function and an exciton binding energy of 11 meV, in agreement with recent calculations.

Using a free particle model, we can determine the extension $w_{FWHM}^{[001]}$, $w_{FWHM}^{[110]}$ of the electron wave function along the two confinement directions [001] and [110] (see Table 1).
Carrier transport in a single GaAs quantum wire structure studied by time-resolved near-field spectroscopy

A. Richter, M. Siiptitz, Ch. Lienau, T. Elsasser, M. Ramsteiner, R. Nötzel, K.H. Ploog* Max-Born-Institut für Nichtlineare Optik und Kurzzeitspektroskopie, Rudower Chaussee 6, D-12489 Berlin, Germany; E-mail: lienau@mbi.fu-berlin.de

Direct studies of the transport of photogenerated electron-hole pairs in semiconductor nanostuctures require both high spatial and temporal resolution. Near-field scanning optical microscopy (NSOM), offering subwavelength spatial resolution in the 100-nm range in combination with time-resolved detection schemes is a particularly promising technique for such experiments. Here we report on the first time-resolved near-field spectroscopic investigation of the carrier dynamics in single gallium arsenide (GaAs)/(AlGa)As sidewall quantum wires.

Quantum wires (QWR) with a lateral width of 60 nm and a thickness of up to 13 nm embedded by a 6-nm GaAs quantum well (QW) were grown by molecular beam epitaxy of GaAs/(AlGa)As multilayer structures on patterned GaAs (311)A substrates along the lateral [01-1] direction. A probe with an aperture diameter of about 200 nm. The laser spectrum overlaps with the excitonic absorption band of the GaAs QW. The excitation positions were varied on a subwavelength scale on the QWR mesa bottom in the vicinity of the QWR.

In our experiments, electron-hole pairs are created by transmitting a fs-Ti:Sapphire laser pulse at 1.614 eV through an NSOM fiber probe with an aperture diameter of about 200 nm. The laser spectrum overlaps with the excitonic absorption band of the GaAs QW. QWR luminescence at 1.54 eV is detected in the far-field as a function of tip position using time-correlated single-photon counting as the tip is scanned perpendicularly to the QWR.

At a temperature of 10 K, QWR luminescence is observed for localized excitation in a narrow region around the QWR, between the two energetic barriers separated by about 800 nm. In this region, the capture into the QWR and the energetic relaxation within the QWR is fast, so that with the temporal resolution of our experiment of 250 ps, the temporal dependence of the QWR luminescence is dominated by the QWR recombinations lifetime of 0.9 ns, independent of excitation position. For excitation outside the barriers, the diffusive transport of excitons across the barriers is strongly suppressed and trapping of carriers generated within the flat area QW is prohibited.

At a temperature of 100 K, a drastically different behavior is found. QWR luminescence is observed for QW excitation at distances of several micrometers away from the QWR. This occurrence of QWR luminescence involves ambipolar drift-diffusion across the barriers. The time-resolved data directly reveal the delayed onset of QWR luminescence for excitation positions between 0.5 and 3 μm.

The experiments directly demonstrate the pronounced influence of spatial bandgap variations on a subwavelength scale on the real-space carrier transfer within the two-dimensional (2D) continuum and thus on the carrier trapping dynamics into the 1D QWR states.

Large third-order optical nonlinearity in Audible dielectric composite films in femtosecond time scale

H.B. Liao, R.F. Xiao, H. Wang, K.S. Wong, G.K.L. Wong, Department of Physics, Hong Kong University of Science & Technology, Clear Water Bay, Kowloon, Hong Kong

We report here the realization of large third-order nonlinear susceptibility, χ(3), from Audible dielectric (SiO2 and TiO2) composite films near the Au percolation threshold. The composite films were prepared by co-sputtering...
