Received 9 March 2011; accepted 17 March 2011

Key indicators: single-crystal X-ray study; $T = 120$ K; mean $\sigma(\text{C}-\text{C}) = 0.003$ Å; H-atom completeness 99%; disorder in main residue; R factor = 0.033; wR factor = 0.075; data-to-parameter ratio = 17.6.

The title compound, poly[[μ -aqua-tetraaqua $\{\mu$ -5-[bis-(carboxylatomethyl)amino]-3-carboxylatomethyl-4-cyanothiophene-2-carboxylato}distrontium(II)] tetrahydrate], $[\text{Sr}_2(\text{C}_{12}\text{H}_6\text{N}_2\text{O}_8\text{S})(\text{H}_2\text{O})_5] \cdot 3.79\text{H}_2\text{O}$, crystallizes with nine- and eight-coordinated Sr^{2+} cations. They are bound to seven of the eight ranelate O atoms and five of the water molecules. The SrO_8 and SrO_9 polyhedra are interconnected by edge-sharing, forming hollow layers parallel to (011). The layers are, in turn, interconnected by ranelate anions, forming a metal-organic framework (MOF) structure with channels along the a axis. The four water molecules not coordinated to strontium are located in these channels and hydrogen bonded to each other and to the ranelates. Part of the water H atoms are disordered. The compound dehydrates very easily and 0.210 (4) water molecules out of nine were lost during crystal mounting causing additional disorder in the water structure.

Related literature

For the effect of strontium on osteoporosis, see Schrooten *et al.* (2003). For a patent describing the synthesis and powder diffraction pattern of the title compound, see Horvath *et al.* (2008). For related strontium carboxylate structures, see, for example: Stahl *et al.* (2006).

Polymeric strontium ranelate nonahydrate

K. Stahl, C. G. Frankaer, A. C. Raffalt, S. R. Sørensen and J. E. T. Andersen

Comment

In recent years it has been found that Sr has a significant influence on the development and growth of bone and the effect of dose on bone structure has been investigated in great detail (Schrooten *et al.* 2003). Strontium ranelate (5-[bis(carboxymethyl) amino]-3-carboxymethyl-4-cyano-2-thiophenecarboxylate) is one promising pharmaceutical compound for treating osteoporosis marketed as Protelos^R by Servier (Horvath *et al.*, 2008). Strontium ranelate is known to form several hydrates with totally nine, eight, seven or four waters (Horvath *et al.*, 2008). The initial dehydration observed here results from an expulsion of O27 or O29 and migration of the remaining water to site O30. As a consequence Sr1 is partially seven-coordinated (c.f. Table 1). The water hydrogen sites connected to O26, O28 and O29 are disordered. In essence, the alternating hydrogen bonding scheme between O28 and O29 is transmitted to a partial O26 - O28 hydrogen bond, and leaves H26B and H29C without hydrogen bond acceptors (c.f. Table 2).

Experimental

Strontium ranelate nona hydrate of 97% purity (Clauson-Kaas A/S) was recrystallized at different temperatures. Recrystallization at temperatures above 353 K appeared to produce the crystals of better quality. Upon cooling to room temperature large crystals of millimeter dimensions were obtained in the saturated solution. However, when the crystals were removed from the solution they rapidly degraded into smaller units of micron dimension. The smaller crystals showed out to contain less crystal water, as compared to the large crystals, presumably seven or five water molecules per formula unit. Thus, wet crystals were quickly transferred to the goniometer for X-ray data collection at 120 K. Several crystal were tried before an acceptable structure refinement was achieved. For all cases of lower quality data the SOF of O30 was about 0.3, confirming its role in the initial dehydration of strontium ranelate and the deterioration of the crystals.

Refinement

The H atoms of the CH₂ groups were placed in calculated positions with C—H = 0.99, and refined as riding atoms. The H atoms of the water molecules were located in difference Fourier maps and refined with restrained O—H distances of 0.82 (2) Å. The H atoms of the partially occupied O30 (SOF=0.210 (4)) could not be located. The H displacement parameters were set to 1.2 (CH₂) or 1.5 (H₂O) times U_{eq} of the corresponding C or O atoms.

Figures

	$l = -18 \rightarrow 18$

Refinement

Refinement on F^2	Primary atom site location: structure-invariant direct methods
Least-squares matrix: full	Secondary atom site location: difference Fourier map
$R[F^2 > 2\sigma(F^2)] = 0.033$	Hydrogen site location: inferred from neighbouring sites
$wR(F^2) = 0.075$	H atoms treated by a mixture of independent and constrained refinement
$S = 1.02$	$w = 1/[\sigma^2(F_o^2) + (0.0383P)^2]$
6617 reflections	where $P = (F_o^2 + 2F_c^2)/3$
375 parameters	$(\Delta/\sigma)_{\text{max}} = 0.002$
21 restraints	$\Delta\rho_{\text{max}} = 1.48 \text{ e } \text{\AA}^{-3}$
	$\Delta\rho_{\text{min}} = -1.23 \text{ e } \text{\AA}^{-3}$

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > 2\sigma(F^2)$ is used only for calculating R -factors(gt) *etc.* and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
