Abstract: Model predictive control (MPC) of a class of nonlinear systems is considered in this paper. We will use Linear Parameter Varying (LPV) model of the nonlinear system. By taking the advantage of having future values of the scheduling variable, we will simplify state prediction. Consequently the control problem of the nonlinear system is simplified into a quadratic programming. Wind turbine is chosen as the case study and we choose wind speed as the scheduling variable. Wind speed is measurable ahead of the turbine, therefore the scheduling variable is known for the entire prediction horizon.

Keywords: Model predictive control, linear parameter varying, nonlinear systems, wind turbines, LIDAR measurements.

1. INTRODUCTION

Model predictive control (MPC) has been an active area of research and has been successfully applied on different applications in the last decades (Qiu and Badgwell (1996)). The reason for its success is its straightforward ability to handle constraints. Moreover it can employ feedforward measurements in its formulation and can easily be extended to MIMO systems. However the main drawback of MPC was its on-line computational complexity which kept its application to systems with relatively slow dynamics for a while. Fortunately with the rapid progress of fast computations, better optimization algorithms, off-line computations using multi-parametric programming (Baotic (2005)) and dedicated algorithms and hardware, its applications have been extended to even very fast dynamical systems such as DC-DC converters (Geyer (2005)). Basically MPC uses a model of the plant to predict its future behavior in order to compute appropriate control signals to control outputs/states of the plant. To do so, at each sample time MPC uses the current measurement of outputs/states and solves an optimization problem. The result of the optimization problem is a sequence of control inputs of which only the first element is applied to the plant and the procedure is repeated at the next sample time with new measurements (Maciejowski (2002)). This approach is called receding horizon control. Therefore basic elements of MPC are: a model of the plant to predict its future, a cost function which reflects control objectives, constraints on inputs and states/outputs, an optimization algorithm and the receding horizon principle. Depending on the type of the model, the control problem is called linear MPC, hybrid MPC, nonlinear MPC etc. Nonlinear MPC is normally computationally very expensive and generally there is no guarantee that the solution of the optimization problem is a global optimum. In this work we extend the idea of linear MPC using linear parameter varying (LPV) systems to formulate a tractable predictive control of nonlinear systems. To do so, we use future values of a disturbance to the system that acts as a scheduling variable in the model. However there are some assumptions that restrict our solution to a specific class of problems. The scheduling variable is assumed to be known for the entire prediction horizon. And the operating point of the system mainly depends on the scheduling variable.

2. PROPOSED METHOD

Generally the nonlinear dynamics of a plant could be modeled as the following difference equation:

\[ x_{k+1} = f(x_k, u_k, d_k) \]  

With \( x_k, u_k \) and \( d_k \) as states, inputs and disturbances respectively. Using the nonlinear model, the nonlinear MPC problem could be formulated as:

\[
\min_{u} \ell(x_N) + \sum_{i=0}^{N-1} \ell(x_{k+i|k}, u_{k+i|k}) \]

Subject to \( x_{k+1} = f(x_k, u_k, d_k) \) \( u_{k+i|k} \in U \) \( \dot{x}_{k+i|k} \in X \)

Where \( \ell \) denotes some arbitrary norm and \( U \) and \( X \) show the set of acceptable inputs and states. As it was mentioned because of the nonlinear model, this problem is computationally too expensive. One way to avoid this problem is to linearize around an equilibrium point of the system and use linearized model instead of the nonlinear model. However for some plants assumption of linear...
model does not hold for long prediction horizons as the plant operating point changes, for example based on some disturbances that act as a scheduling variable. An example could be a wind turbine for which wind speed acts as a scheduling variable and changes the operating point of the system.

\[ x_{k+1} = A(\gamma_k)x_k + B(\gamma_k)u_k + B_d(\gamma_k)d_k + \lambda_k \]

### 2.1 Linear MPC formulation

The problem of linear MPC could be formulated as:

\[
\begin{align*}
\min_{u_0, u_1, \ldots, u_{N-1}} & \quad \|x_N\|_Q + \sum_{i=0}^{N-1} \|x_{k+i}\|_Q + \|u_{k+i}\|_R \\
\text{Subject to} & \quad x_{k+1} = Ax_k + Bu_k \\
& \quad u_{k+i} \in \mathcal{U} \\
& \quad 0 \leq x_k, u_k, d_k \leq 1 \\
& \quad x_k, u_k, d_k \text{ are values of states, inputs and disturbances at the operating point. Therefore the LPV model becomes:} \\
& \quad x_{k+1} = A(\gamma_k)x_k + B(\gamma_k)u_k + B_d(\gamma_k)d_k + \lambda_k \\
\end{align*}
\]

Which could be written as:

\[
\begin{align*}
\lambda_k &= x_{k+1} - A(\gamma_k)x_k - B(\gamma_k)u_k - B_d(\gamma_k)d_k \\
\end{align*}
\]

Now having the LPV model of the system we proceed to compute state predictions. In linear MPC predicted states at step \(n\) is:

\[
\begin{align*}
\hat{x}_{k+n} &= A^n x_k + \sum_{i=0}^{n-1} A^i B u_{k+(n-1)-i} \\
& \text{for } n = 1, 2, \ldots, N \\
\end{align*}
\]

However in our method the predicted state is also a function of scheduling variable \(\Gamma_n = (\gamma_{k+1}, \gamma_{k+2}, \ldots, \gamma_{k+n})^T\) for \(n = 1, 2, \ldots, N - 1\) and we assume that the scheduling variable is known for the entire prediction. Therefore the predicted state could be written as:

\[
\begin{align*}
\hat{x}_{k+1}(\gamma_k) &= A(\gamma_k)x_k + B(\gamma_k)u_k + B_d(\gamma_k)d_k + \lambda_k \\
\end{align*}
\]

And for \(n \in \mathbb{Z}, n \geq 1:\)

\[
\begin{align*}
x_{k+n+1}(\Gamma_n) &= \prod_{i=n}^{\gamma} A(\gamma_{i+1})x_k \\
&+ \sum_{j=0}^{n-1} \left( \prod_{i=n-j}^{1} A(\gamma_{i+1}) \right) B(\gamma_{k+j})u_{k+j} \\
&+ \sum_{j=0}^{n-1} \left( \prod_{i=n-j}^{0} A(\gamma_{i+1}) \right) B_d(\gamma_{k+j})d_{k+j} \\
&+ \left( \prod_{i=n-j}^{0} A(\gamma_{i+1}) \right) \lambda_k(n-1)-j \\
&+ B(\gamma_{k+n})u_{k+n} + B_d(\gamma_{k+n})d_{k+n} + \lambda_{k+n} \\
\end{align*}
\]

In order to summarize formulas for matrices \(\Phi, \Phi_{\lambda}, \mathcal{H}_u, \mathcal{H}_d\), we define a new function as:

\[
\psi(m, n) = \prod_{i=m}^{n} A(\gamma_{i+1}) \\
\]

Therefore the matrices become:

\[
\begin{align*}
\bar{x}_k &= x_k - x_k^* \\
\bar{u}_k &= u_k - u_k^* \\
\bar{d}_k &= d_k - d_k^* \\
x_k^*, u_k^* \text{ and } d_k^* \text{ are values of states, inputs and disturbances at the operating point. Therefore the LPV model becomes:} \\
x_{k+1} &= A(\gamma_k)x_k + B(\gamma_k)u_k + B_d(\gamma_k)d_k + \lambda_k \\
\end{align*}
\]
For modeling purposes, the whole wind turbine is considered as a black box with its inputs being wind speed, blade pitch angle and rotational speed of the rotor, and its output the electrical power. For numerical values of these parameters and other parameters given in this paper, we refer to (Jonkman et al. (2009)).

In which $Q_r$ and $Q_t$ are aerodynamic torque and thrust, $\rho$ is the air density, $\omega_r$ is the rotor rotational speed, $v_r$ is the effective wind speed, $C_p$ is the power coefficient and $C_t$ is the thrust force coefficient. The absolute angular position of the rotor and generator are of no interest to us, therefore we use $\psi = \theta_r - \theta_g$ instead which is the drivetrain torsion.

Having aerodynamic torque and modeling drivetrain with a simple mass-spring-damper, the whole system equation with 2 degrees of freedom becomes:

$$ J_r \ddot{\omega}_r = Q_r - c(\omega_r - \frac{\omega_g}{N_g}) - k \psi $$

$$ (N_g J_g) \dot{\omega}_g = c(\omega_r - \frac{\omega_g}{N_g}) + k \psi - N_g Q_g $$

$$ \dot{\psi} = \omega_r - \frac{\omega_g}{N_g} $$

$$ P_e = Q_g \omega_g $$

In which $J_r$ and $J_g$ are rotor and generator moments of inertia, $\dot{\psi}$ is the drivetrain torsion, $c$ and $k$ are the drivetrain damping and stiffness factors respectively lumped in the low speed side of the shaft and $P_e$ is the generated electrical power. For numerical values of these parameters and other parameters given in this paper, we refer to (Jonkman et al. (2009)).
Linearized model

As it was mentioned in the previous section, wind turbines are nonlinear systems. A basic approach to design controllers for nonlinear systems is to linearize them around some operating points. For a wind turbine, the operating points on the quasi-steady \( C_p \) and \( C_t \) curves are nonlinear functions of rotational speed \( \omega_r \), blade pitch \( \theta \) and wind speed \( v \). To get a linear model of the system we need to linearize around these operating points. Rotational speed and blade pitch are measurable with enough accuracy, however this is not the case for the effect of wind on the rotor. Wind speed changes along the blades and with azimuth angle (angular position) of the rotor. This is because of wind shear and tower shadow and stochastic spatial distribution of the wind field. Therefore a single wind speed does not exist to be used and measured for finding the operating point. We bypass this problem by defining a fictitious variable called effective wind speed \( v_e \) which shows the effect of wind in the rotor disc on the wind turbine. In our two DOFs model only the aerodynamic torque \( Q_e \) and electric power \( P_e \) are nonlinear. Taylor expansion is used to linearize them:

\[
\Delta Q_e(\omega, \theta, v_e) = \frac{\partial Q_e}{\partial \omega} \Delta \omega + \frac{\partial Q_e}{\partial \theta} \Delta \theta + \frac{\partial Q_e}{\partial v_e} \Delta v_e \tag{36}
\]

\[
\Delta P_e = \frac{\partial P_e}{\partial \omega_g} \Delta \omega_g + \frac{\partial P_e}{\partial Q_g} \Delta Q_g \tag{37}
\]

For the sake of simplicity in notations we use \( Q_e \), \( P_e \), \( \theta \), \( \omega \) and \( v_e \) instead of \( \Delta Q_e \), \( \Delta P_e \), \( \Delta \theta \), \( \Delta \omega \) and \( \Delta v_e \) around the operating points from now on. Using the linearized aerodynamic torque, the 2 DOFs linearized model becomes:

\[
\dot{\omega}_r = \frac{a - c}{J_r} \omega_r + \frac{c}{J_r} \omega_g + \frac{k}{J_r} \psi + b_1 \theta + b_2 v_e \tag{38}
\]

\[
\dot{\omega}_g = \frac{c}{N_g J_g} \omega_r - \frac{c}{N_g^2 J_g} \omega_g + \frac{k}{N_g J_g} \psi - \frac{Q_g}{J_g} \tag{39}
\]

\[
\dot{\psi} = \omega_r - \omega_g \tag{40}
\]

\[
P_e = Q_g \omega_g + \omega_g Q_g \tag{41}
\]

A more detailed description of the model and linearization is given in (Mirzaei et al. (2011)).

LPV model

Collecting all the discussed models, matrices of the state space model become:

\[
A(\gamma) = \begin{pmatrix}
a(\gamma) - c & c & -k \\
\frac{J_r}{c} & \frac{1}{c} & -\frac{J_r}{c} \\
\frac{N_g J_g}{1} & -\frac{N_g^2 J_g}{1} & N_g J_g \\
\end{pmatrix}
\]

\[
C = \begin{pmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & Q_{go} & 0
\end{pmatrix}
\]

\[
B(\gamma) = \begin{pmatrix}
b_1(\gamma) & 0 & 0 \\
0 & -\frac{1}{J_g} & 0 \\
0 & 0 & 0 \end{pmatrix}
\]

\[
D = \begin{pmatrix}
0 & 0 & 0 \\
0 & 0 & 0 \\
0 & \omega_{gm} & 0
\end{pmatrix}
\]

In which \( x = (\omega_r, \omega_g, \psi)^T \), \( u = (\theta, Q_g)^T \) and \( y = (\omega_r, \omega_g, P_e)^T \) are states, inputs and outputs respectively. In the matrix \( B \), parameter \( b_1 \) is uncertain. Therefore the uncertain linear state space model becomes:

\[
\dot{x} = A(\gamma)x + B(\gamma)u \]

\[
y = Cx + Du
\]

3.2 Control objectives

The most basic control objective of a wind turbine is to maximize captured power during the life time of the wind turbine. This means trying to maximize captured power when wind speed is below its rated value. This is also called maximum power point tracking (MPPT). However when wind speed is above rated, control objective becomes regulation of the outputs around their rated values while trying to minimize dynamic loads on the structure. These objectives should be achieved against fluctuations in wind speed which acts as a disturbance to the system. In this work we have considered operation of the wind turbine in above rated (full load region). Therefore we try to regulate rotational speed and generated power around their rated values and remove the effect of wind speed fluctuations.

3.3 Offset free control

Persistent disturbances and modeling error can cause an offset between measured outputs and desired outputs. To avoid this problem we have employed an offset free reference tracking approach (see Muske and Badgwell (2002) and Pannocchia and Rawlings (2003)). Our RMPC solves the regulation problem around the operating point. However we regulate around the operating point \( (x^*_k, u^*_k) \) which results in offset from desired outputs. To avoid this problem in our control algorithm we shift origin in our regulation problem to \( x^*_k \) and \( u^*_k \) instead. In order to find new origins, we have augmented linear model of the plant with a disturbance model that adds fictitious disturbances to the system. The fictitious disturbances compensate the difference between measured outputs and desired outputs.

State space model of the augmented system is:

\[
\hat{x}_{k+1} = \hat{A} \hat{x}_k + \hat{B} u_k \tag{44}
\]

\[
y_k = \hat{C} \hat{x}_k + D u_k \tag{45}
\]

in which the augmented state and matrices are:
Table 1. Performance comparison between gain scheduling approach and linear MPC

</tbody>
</table>

\[
\begin{align*}
\dot{x}_k &= \begin{pmatrix} x_{k+1} \\ d_{k+1} \\ p_{k+1} \end{pmatrix} \\
\ddot{A} &= \begin{pmatrix} A & B_d & 0 \\ 0 & A_d & 0 \\ 0 & 0 & A_p \end{pmatrix} \\
\ddot{B} &= (B \ 0 \ 0)^T \\
\ddot{C} &= (C \ 0 \ C_p)
\end{align*}
\]  

$\dot{x}_k$, $\ddot{d}_k$ and $\ddot{p}_k$ are system states, input/state and output disturbances respectively. $(A, B, C, D)$ are matrices of the linearized model, $B_d$ and $C_p$ show effect of disturbances on states and outputs respectively. $A_d$ and $A_p$ show dynamics of input/state and output disturbances. For more information and how to choose these matrices we refer to (Muske and Badgwell (2002)) and (Pannocchia and Rawlings (2003)). Since the disturbances are not measurable, an extended Kalman filter is designed to estimate them. The estimated disturbances are used to remove any offset between desired outputs and measured outputs. Based on this model and estimated disturbances, $x^0_k$ and $u^0_k$ which are offset free steady state input and states can be calculated:

\[
\begin{pmatrix} A - 1 & B \\ C & D \end{pmatrix} \begin{pmatrix} x^0_k \\ u^0_k \end{pmatrix} = \begin{pmatrix} -B_d \ddot{d}_k \\ -C_p \ddot{p}_k \end{pmatrix}
\]  

After calculating these values, we simply replace $\dot{x}_k$ and $u_k$ in (18) with $x^0_k$ and $u^0_k$ which results in:

\[
\lambda_k = x^0_{k+1} - A(\gamma_k)x^0_k - B(\gamma_k)u^0_k - B_d(\gamma_k)d^0_k
\]

4. SIMULATIONS

In this section simulation results for the obtained controller are presented. The controller is implemented in MATLAB and is tested on a full complexity FAST (Jonkman and Jr. (2005)) model of the reference wind turbine (Jonkman et al. (2009)). Simulations are done with realistic turbulent wind speed, with Kaimal model (iec (2005)) as the turbulence model and TurbSim (Jonkman (2009)) is used to generate wind profile. In order to stay in the full load region, a realization of turbulent wind speed is used from category C of the turbulence categories of the IEC 61400-1 (iec (2005)) with 18m/s as the mean wind speed.

4.1 Stochastic simulations

In this section simulation results for a stochastic wind speed is presented. Control inputs which are pitch reference $\theta_{in}$ and generator reaction torque reference $Q_{in}$ along with system outputs which are rotor rotational speed $\omega_r$ and electrical power $P_e$ are plotted in figures 3-6 (red-dashed lines are results of linear MPC and solid blue lines show the results of the proposed approach.) Simulation results show good regulations of generated power and rotational speed. Table 1 shows a comparison of the results between the proposed approach and MPC approach based on linearization at each sample point (Henriksen (2007)).

As it could be seen from the table and figures, the proposed approach gives better regulation on rotational speed and generated power (smaller standard deviations) while maintaining a smaller shaft moment and pitch activity.
