Abstract

The paper presents the background and the input parameters from research surveys and the commercial fishery to the
assessment of the Greenland halibut stock component in NAFO Subarea 0 + Div. 1A offshore + Div. 1B-1F. During
2006-2009 catches have been around 24,000 tons. Catches increased to 26,900 tons in 2010 and has been at that
level since. Survey trawlable biomass in Div. 0B decreased between 2011 and 2013 while biomass and recruitment
increases in the Greenland shrimp fish survey and the recruitment of the 2012 year class in the entire survey area was
the third largest in the time series. A combined standardized CPUE series from Div. 0A + 1AB has been stable since
2002. A combined CPUE series from Div. 1CD+0B decreased between 2011 and 2012 but increased slightly in 2013 and
is above the level in 1990-2004. A combined standardized CPUE series from SA0 and 1 combined has been increasing gradually since 1997 and was in 2013 at the third highest level seen since 1990. CPUE series from the gill
net in Div. 0A and Div. 0B were close to or at the highest level in the time series.

1. TAC, description of the fishery and nominal catches.

TAC

Between 1979 and 1994 a TAC was set at 25,000 tons for SA 0+1, including Div. 1A inshore. In 1994 it was decided to make separate assessments for the inshore area in Div. 1A and for SA 0 + Div. 1A offshore + Div.1B-1F. From 1995-2000 the advised TAC for the latter area was 11,000 tons but the TAC was fished almost exclusively in Div. 0B and Div. 1CD. In 2000 there was set an additional TAC of 4,000 tons for Div. 0A+1AB for 2001 and the TAC on 11,000 tons was allocated to Div. 0B and Div. 1CF. The TAC in Div. 0A+ Div. 1AB was in 2002 increased to 8,000 tons for 2003. Total advised TAC for 2004 and 2005 remained at 19,000 tons. In 2006 the advised TAC in Div. 0A+1AB was increased by 5,000 tons to 13,000 tons. The total advised TAC remained at 24,000 tons in 2008 and 2009. In 2010 the TAC for Div. 0B+ Div. 1CF was increased by 3,000 tons to 14,000 tons and the total TAC for Subarea 0+1 was 27,000 tons. The TAC remained at 27,000 tons in 2011-2013. In 2014 the TAC was increased by 3,000 tons to 16,000 tons in in Div. 0A+ Div. 1AB and the total TAC for the area (excluding inshore areas in Div. 1A) is 30,000 tons (Fig.1)
**Catches in SA 0 + Div. 1A offshore + Div.1B-1F**

During the period 1982-1989 nominal catches of Greenland halibut in SA 0 + Div. 1A offshore + Div.1B-1F fluctuated between 300 and 4,500 tons. Catches increased from 2,927 tons in 1989 to 11,633 tons in 1990. Catches remained at that level in 1991 but increased again in 1992 to 18,457 tons. During 1993-2000 catches have fluctuated between 8,250 and 11,750 tons. Catches increased to 13,760 tons in 2001 and further to 19,716 tons in 2005. In 2006 catches increased to 24,164, remained at that level in 2007 but decreased slightly to 22,071 tons in 2008. Catches increased again to 24,805 tons in 2009 and further to 26,934 tons in 2010 and catches remained at that level in 2011 - 2012 – 27,260 tons in 2012 but increased to 28,062 tons in 2013 (Fig. 1).

The increase in catches from 1989 to 1990 was due to a new trawl fishery by Canada and Norway and increased effort by Russia and Faeroe Islands in Div. 0B, while the increase from 1991 to 1992 was caused by a further increase in effort by Russia in Div. 0B and an increase in fishing activity in SA 1. The increase in catches between 2000 and 2006 was primarily due to an increase in effort in Div. 0A and Div. 1A. The increase in catches between 2009 and 2010 was due to increased effort in Div. 0B and 1CD. The increase in catches between 2012 and 2013 was primarily due to increased effort in inshore areas in Div. 1D.

**Catches in SA 0**

In 1983 annual catches in SA 0 were about 4,500 tons. Catches then dropped to a level of 1,000 tons or lower, where they remained until they increased from 1,087 tons in 1989 to 9,753 tons in 1990. Catches decreased in 1991 to 8,745 tons, to increase again in 1992 to 12,788 tons. Catches then decreased gradually to 3,233 tons in 1995 and fluctuated between 3,924 and 5,438 tons between 1996 and 2000. Until 2000 almost all catches in SA 0 were taken in Div. 0B. In 2001 a commercial fishery started in Div. 0A. Catches in SA 0 increased to 8,107 tons in 2001 and further to 9,201 tons in 2003 and remained at that level in 2004 and 2005. Catches increased to 12,319 in 2006 but decreased slightly to 11,489 tons in 2007 and further to 10,432 tons in 2008. Catches increased again to 12,400 tons in 2009 and further to 13,225 tons in 2010. Catches decreased slightly in 2011 to increase again in 2012 to 13,331 tons. Catches remained at that level in 2013 (13,351 tons, excluding 315 tons taken in Cumberland Sound) (Table 1).

The increase in catches seen since 2000 was mainly due to an increased effort in Div. 0A where catches increased from a level of about 300 ton, where they have been since 1996 (trawl fishery not officially reported), to 3,073 tons in 2001 and further to 4,142 tons in 2003. Catches remained at that level in 2004 and 2005. In 2006 catches increased to 6,634 tons due to increased effort, but decreased to 6,173 tons in 2007 and further to 5,257 tons in 2008. Catches increased again in 2009 to 6,627 tons and remained at that level in 2010 – 2013, - 6,314 tons in 2013 (Table 1).

About half of the catches in Div. 0A in 2013 were taken by trawlers, mainly twin trawlers, while the other half was taken by gill net. The long lines fishery in the area only amounted to 9 tons. The fishery was prosecuted by Canadian vessels.

Catches in Div. 0B 2013 amounted to 7,037 tons which is at the same level as in 2011 and 2012. About 1/3 was taken by gill net, single trawl and twin trawl, respectively. All catches were taken by Canadian vessels. 315 tons reported from Cumberland Sound Cumberland Sound are not included.

**Catches in SA 1**

The catches in Subarea 1 (Div. offshore 1A + Div. 1B-1F) were below 2,500 tons during 1982-1991. In 1992 catches increased to 5,669 tons, decreased to 3,870 tons in 1993 and increased again in 1994. During 1995-1999 catches were around 4,500-5,000 tons. Catches increased to 5,728 tons in 2000, remained at that level in 2001 and increased gradually to 9,495 tons in 2003 and remained at this level in 2004 and 2005. Catches increased to 11,945 tons in 2006 due to increased effort by Greenland in Div. 1AB and remained at that level in 2007 and 2008. In 2009 catches amounted to 12,405 tons and increased further to 13,709 tons in 2010 and remained at that level in 2011 and 2012. Catches increased to 14,711 tons in 2013 (Table 2). Almost all catches have been taken offshore. However, the inshore catches increased from 440 tons in 2012 to 1289 tons in 2013 primarily due to an increased effort inshore in Div. 1D (Fig. 1).

Catches in Div. 1AB (mainly in Div. 1A) increased gradually from 575 tons in 2001 to 4,007 tons in 2003 and remained at that level in 2004-2005. Catches increased again in 2006 to 6,223 and remained at that level during 2007-2013 (6,500...
tons in 2013). All catches were taken off shore by trawlers from Faeroe Islands, Russia (SCS 14/13) and Greenland (SCS 14/12).

Catches in Div. 1CD have been stable around 5,600 tons during 2000 to 2009, but catches increased to 7,247 in 2010 due to increased effort. Catches remained at that level in 2011 and 2012 but increased to 8,227 tons in 2013. Catches were taken by vessels from Greenland (SCS 14/12), Norway, EU-Germany and Russia (SCS 14/13). All most all catches offshore were taken by trawl except 75 tons that was taken by longline. Inshore catches in Div. 1B-1F, increased from 400 tons in 2012 to 1289 tons mainly due to increased effort in Div. 1D (1024 tons in 2013).

Reported discards in the trawl fishery is small, normally < 1% of the total catch.

2. Input data

2.1 Research trawl survey

Div. 1C-1D GHL-survey

Since 1997 Greenland has conducted stratified random bottom trawl surveys for Greenland halibut in September-October in NAFO Div. 1C-D at depth between 400 and 1500 m. In 2013 only Div. 1D was covered by just 27 valid hauls (SCR 14/02) and the survey is considered incomplete and not used for assessment because the biomass in Div. 1C not could be determined with a reasonable degree of precision. The proportion of the biomass found in Div. 1D has been varying during the years between 65 and 85%. And although the biomass in Div. 1D is at the same level as in 2012 the standardized trawl CPUE for Div. 1CD increased between 2012 and 2013 (Fig. 12c) indicating that a substantial part of the biomass could be found in Div. 1C.

The biomass of Greenland halibut in Div. 1D 43 457.5 tons which is at the same low level as in 2012 (42 370.6 tons) where the total biomass was estimated as 64 948.8 tons, which was a decrease compared to 86 591 tons in 2011 and the lowest in the time series since 2000 (Fig. 2a, 2c). The abundance in 2013 was estimated at 32.372*10^6. The overall length distribution was dominated by a single mode at 50 cm, where the length distribution use to be monomodal with a mode around 47-49 cm (Fig. 2d).

Greenland deep sea survey in Baffin Bay (Div. 1A)

There was no survey in 2013. Greenland has conducted surveys primarily aimed at Greenland halibut in the Baffin Bay in 2001, 2004 and 2010. The biomass and abundance of Greenland halibut was in 2010 estimated as 79.332 tons and 1.04*10^5 specimens, respectively (SCR 11/10). The surveys did not cover the same areas but a comparison of the abundance and biomass in areas covered both in 2001 and 2010 showed a small increase in biomass from 46.521 tons in 2001 to 52.428 tons in 2010 while there was a decrease in abundance from 101.8 mill. in 2001 to 63.5 mill. in 2010. The biomass has hence been relatively constant while there were significantly more and smaller fish in 2001. The biomass in the area covered both in 2004 and 2010 was estimated to 47.244 tons and 38.632 tons, respectively while the abundance was estimated at 58.8 mill. and 54.4 mill., respectively. The length in 2010 ranged from 20 cm to 105 cm. The overall length distribution (weighted by stratum area) was totally dominated by a mode at 45 cm, while the mode was at 46 cm at depths > 800 m. Generally the length distributions in the deeper depth strata were dominated by a single mode and fish size increased with depth as seen in previous surveys.

Canadian deep sea surveys in Baffin Bay (Div. 0A) and Davis Strait (Div. 0B)

There was no survey in Div. 0A in 2013. Canada has conducted 7 surveys in the southern part of Div. 0A, beginning in 1999. The biomass has varied from 68,760 tons to 86,176 tons (Fig. 2ef). The 2012 estimate of biomass is 102,486 t. However, one very large set in a depth stratum that comprises 30% of the area covered contributed to this increase. With this set removed the biomass estimate drops 15% to 86,874 t. Also, the 2006 survey suffered from poor coverage and two of the four strata that were missed fell within the depths 1001-1500 m, these strata had accounted for 11,000 – 13,000 tons of biomass in previous surveys. The abundance in 2012 was estimated at 1.31 x 10^8 (1.02 x10^8 with outlier removed). This compares to previous highs of 1.19 x 10^8 in 1999 and 2001 (Fig. 2g). Mean biomass per tow
is not influenced by the large set to the same extent as total biomass. In 2012 it was 2.07 t/ km² (1.76 t/ km² with outlier removed) (2 hi). This is similar to previous highs of 2.00 t/ km² and 1.94 km² in 2001 and 2004, respectively. The overall length distribution ranged from 6 cm to 90 cm with a small mode at 21 cm and a larger one at 42 cm, slightly higher than seen in previous surveys (64% < 45 cm (57% with outlier removed) (Fig. 2J) (SCR 13/033).

In 2012 the survey also covered the northern part of Division 0A from 73°N to 75°35’N, which had been surveyed previously in 2010 and 2004. The 2012 estimates of biomass and abundance were 82,669 t (S.E. 6695 t) and 9.4 x 10⁷, respectively. This is a significant increase from previous estimates that ranged from 45,877 t to 46,689 t. This increase is due to the increase in survey area due to good weather and little ice in the northern strata. Mean biomass per tow was also higher in 2012, 1.26 t/km² compared to 0.85 and 1.18 t/km² in 2004 and 2010, respectively. Mean biomass per tow has varied without any clear trend within depth strata across survey years (SCR 13/033). Length ranged from 18 to 78 cm with a mode at 45 cm and a smaller mode at 21 cm, similar to that observed for 0A-South; 46% were <45 cm (Fig. 2k) (SCR 13/033).

Division 0B was surveyed in 2013 for the fourth time by R/V Pamiut. Previous surveys were conducted in 2000, 2001 and 2011, respectively. Prior to this there had been a survey conducted in 1986 using the RV Gadus Atlantica. Total estimated biomass and abundance were in 2013 57,765 tons and 5.60 x 10⁷, respectively. Biomass had decreased compared to previous two surveys and was back at the level seen in 2000 (Fig. 2I) and the abundance was lower than in 2000. Biomass and abundance were reduced in all strata compared to 2011. Lengths ranged from 6 cm to 92 cm with 30% < 45 cm. The length distribution had a single mode at 48 cm (Fig 2m. (SCR 14/020).

**Greenland shrimp-fish-survey**

Since 1988 annual trawl surveys with a shrimp trawl have been conducted off West Greenland in July-September. The survey covers the area between 59°N and 72°30’N (Div. 1A-1F), from the 3-mile limit to the 600-m depth contour line. The survey area was restratified in 2004 based on better information about depths. All biomass and abundance indices have been recalculated. The recalculation did not change the trends in the development of the different stocks. The trawl was changed in 2005 but the data have not been adjusted for that and the two time series are not directly comparable.

Estimated total trawlable biomass of Greenland halibut in the offshore areas has during 2005-2012 fluctuated between 49,779 and 25,644 tons estimated in 2012. The 2012 estimate is a decline from 40,003 tons in 2011. The biomass was back at the 2011 level in 2013 – 39,383 tons (Fig. 2n).

The abundance was estimated at 534 mill. in 2011 which was the highest in the time series. The abundance decreased to 187 mill. in 2012 which is the lowest in the 2005-2012 time series and not seen lower since 1997 although the figures are not directly comparable. The abundance increased again in 2013 to 521 mill. The increase was seen in all division except Div. 1D-1F and the increase was more pronounced in Div. 1A.

**Recruitment**

A recruitment index was estimated for the Greenland shrimp – fish survey. By means of the Petersen-method ages 1, 2 and 3+ were separated in the survey catches. The number of one-year-old fish in the total survey area including Disko Bay increased gradually from 1996 to a peak of 500 million in 2001. The number of one-year old fish was in 2011 estimated as 330 mill. which is an increase from 310 mill in 2010 and the highest in the time series. The increase between 2010 and 2011 was caused by an increase in abundance both offshore in Div. 1A and inshore in Disko Bay. In 2012 the 2011 year class was estimated to 175 mill. - the lowest estimate since 1996 and at the level of the early 90’es. The recruitment increased again in 2013 where the 2012 year-class was estimated at 444 mill. which is the third largest estimate in the time series (Fig. 3).

To allow comparison of abundance throughout the time series, the 2005 to 2013 catches were divided by a conversion factors to adjust the new Cosmos trawl catches to the old Skjervoy trawl catches. For Greenland halibut the conversion were length dependent and x in the equations is the individual fish length. Greenland halibut conversion factor: 0.0404x+0.6527.
The offshore recruitment has been rather stable between 2003 and 2010. The recruitment increased to the highest level in the time series in 2011 but decrease to lowest level seen since 1997 (1996 year-class) in 2012. The offshore recruitment (2012 year-class) increased again in 2013 and the estimate is the second largest in the time series. In 2013 79% of the one year old fish was found in the off shore areas. The increase in recruitment between 2012 and 2013 was seen in all divisions except Div. 1C-1F (Fig. 4).

In Disko Bay the recruitment has been decreasing between 2003 and 2008 and increased since then to the highest level seen since 2001 in 2011. In 2012 the recruitment decreased again to the lowest level seen since 2008 to increase again in 2013, but not as significantly as in the off shore areas (Fig. 4).

Generally there is a steep decline between abundance at age 1 and age 2 and 3+ which also was observed in the 2013 survey. Further, it has been noted, that the year-classes estimated to be a very strong year-class at age 1 have not shown up as a particularly strong year-classes at age 5-8 in the fishery catches or in the 1CD survey for Greenland halibut.

Biological information
Information about maturity and feeding of Greenland halibut sampled during 2001-2013 in Div. 1AB and Div. 1CD on board Russian Federation trawlers was presented (SCR 14/XX). Generally the proportion of maturing fish was low in Div. 1AB, while it was somewhat higher in Div. 1CD especially among males. Spawning individuals were observed in October-November in Div. 1CD. In Div. 1AB the food was dominated by fish and shrimps while fish and squids dominated in Div. 1CD.

2.2 Commercial fishery data.

Length distribution

SA 0

No length distributions were available from the fishery in SA 0 in 2013

SAI

Length frequencies were available from the Greenlandic and the Russian trawl fishery in Div. 1A and from the Russian (SCS 14/13), Greenlandic and Norwegian trawl fishery and from the inshore fishery in Div. 1D.

In Div. 1A the mode was at 48 cm in the Russian trawl fishery (Fig. 6) and at 51 and 53 cm in the Greenlandic fishery (Fig. 7). In recent years the trawl catches have been dominated by fish on 44-52 cm.

In Div. 1D the catches by Norway had modes at 52 and 55 cm, the mode in the Russia fishery was at 48-50 cm while it was at 51 cm in the Greenland fishery, respectively (Fig. 8, 9, 10a). The catches seems to be composed of slightly larger fish than in previous years where the mode was around 47-50 cm. The inshore catches in Div.1D were composed of fish between 35 and 83 cm with a mode at 53 cm (Fig. 10b).

Age distribution.

There is considerable uncertainty about accuracy in the current age reading methods (see section in STACREC 2011 report) and the age reading procedure is currently under revision hence no age based analysis are presented.
Catch rate

The fleets used for standardization of catch rates are grouped according to NAFO’s protocol:

Code for country:

2 CAN-MQ Canada Maritimes & Quebec
3 CAN-N Canada Newfoundland
5 FRO Faroe Islands
6 GRL Denmark Greenland
7 E/DNK Denmark Mainland
8 E/FRA-M France Mainland
9 FRA-SP France St. Pierre et Miquelon
10 E/DEU Federal Republic of Germany
14 JPN Japan
15 NOR Norway
16 E/POL Poland
18 ROM Romania
19 E/ESP Spain
20 SUN Union Soviet Socialist Republics
27 CAN-M Canada Maritimes
28 CAN-Q Canada Quebec
31 E/LVA Latvia
32 E/EST Estonia
33 E/LTU Lithuania
34 RUS Russia
38 EU European Union
39 CAN Canada
40 CAN-CA Canada Central & Arctic

All vessels fishing in SA1 have been given the code 6 (Greenland).

Code for Trawl Gear:

Bottom otter trawl (charters), 8, OTB
Bottom otter trawl (side or stern not specified), 10, OTB
Bottom otter trawl, 12, OTB-2
Otter twin trawl, 192, OTT

Code for Tonnage:

0 Not known
2 0-49.9
3 50-149.9
4 150-499.9
5 500-999.9
6 1000-1999.9
7 2000 and over

Ex. Code 401927 is 40: Canada Central & Arctic, 192: Otter twin trawl, 7: Over 2000 Gross Tonnage

SA0

There have been frequent vessel changes in this fishery over the years and the catch from single and double trawl gear was often aggregated as “otter trawl” catch when this gear was first introduced to the fishery in the early 2000s. Very few of the vessels operating in the fishery in 2013 have been in the fishery for more than 3 years. A standardized catch rate is produced using a General Linear Model. The model was updated in 2014 with the 2013
data. Catches (t) and hours fished with values less than 10 were removed.

Div. 0A
In Div. 0A the standardized CPUE index have been increasing between 2010 and 2013, but generally the
standardized catch rates have been relatively stable since 2002 (Fig. 2a) (Appendix 1). The increase could also be
seen in the un-standardized catch rates for both single and twin trawl gears (Fig. 11a).

Standardized CPUE for Gill nets has been increasing gradually between 2006 and 2011 and has been stable since
then (Fig. 12b) (Appendix 4).

Un-standardized CPUE for gillnets has increased gradually from 5.36 t/100 nets in 2004 to 12.79 t/100 nets in 2011
but decrease to 11.8 t/100 nets in 2012 and stayed at that level in 2013 (Fig. 11c).

Div. 0B
In Div. 0B the overall CPUE index increased to the highest observed level in 2009 but declined in 2010 to increase
slightly in 2011 but decreased again in 2012 to the low level seen in 2003 and 2004 (Fig. 12d) (Appendix 5). The
index increased slightly in 2013. The un-standardized catch rates for both twin and single trawls also increased
slightly between 2012 and 13 (Fig. 11b).

The standardized CPUE for gill net in Div. 0B has been increasing since 2007 and was in 2013 at the highest level
in the time series (Fig. 12b) (Appendix 8).

Un-standardized CPUE for gillnets remained relatively stable at 3–4 t/100 nets from 2003 to 2008, then increased to
6.54 t/100 nets in 2010. In 2011 the CPUE dropped slightly to 5.98 t/100 nets to increase again in 2012 to 6.7 t/100
net, the highest level in the time series but decreased slightly in 2013 to 6.2 t/100 net (Fig. 11c).

SA1
Un-standardized catch rates were available for the Greenland trawl fishery in Div. 1A and 1D (SCS 14/12). Further,
catch rates were available from logbooks submitted by all countries to the Greenland authorities. Standardized catch
rates were available from the trawl fishery in Div. 1AB and 1CD. Until 2008 the fleets in the catch rate analysis have
been grouped by nation, but information about gross tonnage is now available in the Greenland logbook database and
the fleets are grouped based on size and gear according to NAFO’s protocol. This has not changed the trends in the
CPUE series but the SE and CV of the estimates have been reduced significantly. In the GLM model catches (t) and
hours fished with values less than 10 are removed.

Div. 1AB
Un-standardized catch rates from large (>2000 GT) trawlers that take most of the catch in Div. 1A have been relatively
stable since 2005 around 0.93 ton/hr but showed a slight increase between 2009 to 2010 and increased substantially
between 2010 and 2011 to 1.4 ton hr⁻¹ and 1.3 ton hr⁻¹ for single trawlers and twin trawlers, respectively. Since the
CPUE has declined gradually to 1.2 ton/ for both gear types (Fig. 11e)

Standardized catch rate series, based on logbook data from the Greenland authorities, were available for the offshore
trawl fishery in Div. 1AB for the period 2002-2013. Standardized catch rates in Div. 1AB has been declining between
2006 and 2008 but has been increasing since then and was in 2011 on the highest level in the time series. The CPUE
decreased slightly in 2012 and 2013 but is still at a high level. (Fig. 12a, Appendix 2).

Div. 1CD
The un-standardized catch rates for all trawlers fishing in Div. 1CD increased between 2011 and 2012, except for
trawlers > 2000 tons trawlers. The catch rates increased significantly for > 2000 tons single trawlers in 2013 and the
smaller single trawlers also showed an increase, while the twin trawlers showed minor decreases between 2012 and 2013.
The high catch rates for > 2000 GT single trawlers in 1988 and 1989 is from a single large vessel (4000 GT) and the
decrease in catch rates in 2007 for large > 2000 GT twin trawlers was caused by a significant decrease in catch rates
from one out of two vessels (Fig. 11f).
Standardized catch rate series, based on logbook data from the Greenland authorities, were available for the offshore trawl fishery in Div. 1CD for the period 1988-2013 (Fig.12c). Standardized catch rates in Div. 1CD decreased gradually from 1989-1997 but have shown an increasing trend since then. CPUE decreased between 2009 and 2010 but increased again in 2011-2013 and the CPUE is at the high level seen in 1989 (Appendix 6).

Combined standardized catch rate in Div. 0A-1AB
The combined Div. 0A+1AB standardized CPUE series decreased slightly between 2009 and 2010 to increase again in 2011, but were back at the 2010 level in 2012 and 2013. The catch rate has, however, been relatively stable since 2001 (Fig. 12a) (Appendix 3).

Combined standardized catch rate in Div. 0B-1CD
The combined Div. 0B+1CD standardized CPUE series has been stable in the period 1990-2004. The CPUE gradually increased to peak in 2009. CPUE decreased slightly between 2009 and 2010 to increase again in 2011 but decreased in 2012 to increase again in 2013. The estimate is, higher than the estimates from 1990-2004. The high catch rates seen in 1988 and 1989 are from a single very large trawler fishing in Div. 1CD (Fig. 12e) (Appendix 7).

Combined standardized trawl catch rate for SA 0+1
The combined catch rate has been gradually increasing since 1997 and was in 2013 at the third largest level seen since 1989 (Fig 12g).

It is not known how the technical development of fishing gear, etc. has influenced the catch rates. There are indications that the coding of gear type in the log books is not always reliable, which also can influence the estimation of the catch rates. Further, due to the frequency of fleet changes in the fishery in both SA0 and SA1 and change in fishing grounds in Div. 0A and 1A, both the un-standardized and the standardized indices of CPUE should, however, be interpreted with caution.

3. Assessment

A Greenland halibut age determination workshop in 2011 concluded that there is considerable uncertainty about accuracy in the current age reading methods (see section in STACRE C 2011 report) and the age reading procedure is currently under revision hence no age based analysis are up dated.

3.1 Yield per Recruit Analysis.

The level of total mortality has in 1994-1996 been estimated by means of catch-curves using data from the offshore longline fishery in Div. 1D. Z was estimated from regression on ages 15-21. A relative F-at-age was derived from the catch curve analysis, where the trawl, longline and gillnet catches were weighed and scaled to the estimated stock composition. In all three years STACFIS considered that the estimation of Z was based on too limited samples and represented too small a part of the fishery and that the outcome of the catch curve analysis was too uncertain to be used in the yield per recruit analysis. No Yield per Recruit Analysis were made due to lack of age data.

3.2 XSA.

Extended Survivors Analysis
An XSA has been run unsuccessfully several times during the 1990’ies, using a survey series covering 1987-1995 as tuning. STAFIS considered the XSA’s unsuitable for an analytic assessment due to high log-catchability residuals and S.E.’s and systematic shift in the residuals by year. Further, a retrospective plot of Fbar showed poor convergence. In 1999 the XSA analyses was rerun including the latest two years surveys (1997-1998, new vessel and gear) but the outcome of the analysis did not improve.

An XSA analysis was run using the stock data for SA 0+1, calibrated with trawl survey data (age 5-15) from the Greenland deep sea surveys (1997-2001) in Div. 1CD. The assessment results were considered to be provisional due to problems with the catch-at-age data and the short time series, the assessment is, however, considered to reflect the
dynamics in the stock. The rate of exploitation had been relatively stable in recent years between 0.2-0.3 ($F_{\text{bar}}$ 7-13). The input parameters to the analysis and the outcome of the analysis is given in SCR 02/68.

The XSA was run again in 2003 with the 2002 survey and catch data and updated catch data from 2001 (very small changes). The assessment results were considered to be provisional due to problems with the catch-at-age data and the short time series. The assessment was, however, considered to some extent to reflect the dynamics in the stock. The rate of exploitation had been relatively stable in recent years between 0.2-0.3 ($F_{\text{bar}}$ 7-13). The summary of the XSA is given in SCR 02/68.

The XSA was not run this year as no catch-at-age data were available for 2003-2012.

3.3 Spawning stock/recruitment relations.

A spawning stock/recruitment plot based on the available observations from the joint Japan/Greenland survey and the Greenland survey is shown in Fig. 5. No further analysis of spawning stock recruitment relationships have been made due to few observations distributed on two different surveys, poor estimate of spawning stock biomass (survey trawls only take a very small proportion of the mature fish), poor estimates of ages of old fish, the survey covers only a restricted part of the area covered by the assessment, and knife edge maturity ogive was applied. Further, the age of the recruits is poorly estimated (the Petersen method). The plot was not updated because there was no aging of Greenland halibut in the recent surveys.

3.4 Relative F

A relative F was estimated from the catches and the swept area biomass estimates from Div. 1CD (Catch/Biomass) (Fig. 13). F has fluctuated between 0.02 and 0.17 but has been relatively stable around 0.08 since during 1997-2011, but F increased to 0.11 in 2012 due to a decline in the estimated biomass. There biomass was poorly estimated in 2013 but F is probably at the same level as in 2012.

A relative F cannot be estimated in SA0 because a large fraction of the catches are taken by gill nets that generally catch larger fish than the commercial trawl and the trawl surveys. The trawl fishery seems, however, not to affect the catch rates in the gill net fishery that has been stable in recent years.

3.5 ASPIC

ASPIC was run in 1999 with standardized CPUE data and a biomass index as inputs. Three CPUE series were available, one series covering Div. 0B during the period 1990-1998, one covering Div. 1CD during the period 1987-1998 and a series combining the two data sets. The biomass index was from 1CD and covered the period 1987-1995 and 1997-1998. Several runs showed that the combined CPUE series from Div. 0B+1CD fitted the total catch data best in terms of $r^2$ and “total objective function”. Runs with biomass alone gave relatively bad fits in terms of “total objective function” and $r^2$ and the modeled population trajectory declining drastically over the period. Runs with the CPUE series from 0B gave unrealistically high $B_{\text{msy}}$ and negative $r^2$. The run with the combined CPUE series showed, however, that sensitivity analysis should be run, because “the B1-ratio constraint term contributed to loss”. Several runs with different realistic values for the constraint did not solve the problem. Further, the coverage index and nearness index was equal in all runs. Several runs with different constraints on r and MSY were tried but it did not change the outcome of the analysis. Removing the three first years from the input data gave negative $r^2$. To get measures of variance the run with the combined CPUE series was bootstrapped (500 re-samplings).

The results showed that estimated fishing mortalities 1987-1998 have been less than the (bias-reduced) estimate of $F_{\text{msy}}$ (0.22) except for one year (1992). A number of essential parameters are quite imprecisely estimated ($r, q, F_{\text{msy}}$), and it is considered that the estimates of MSY and $F_{\text{msy}}$ were not precise enough to be used.

An ASPIC was run in 2009, but the outcome of the analysis did not change significantly from the analysis in 1999, mainly because there is very little contrast in the input data and the data series were relatively short.
The ASPIC Fox model was tested again during this assessment. Three different formulations were run: 1) one was with the 0B + 1CD CPUE series and the 0B +1CD catch for 1988-2011; 2) with two 1CD survey series (1988-1995 and 1997-2011) and 1CD catch (1988-2011); and 3) one 1CD survey series (1997-2011) and 1CD catch (1988-2011). The first formulation using CPUE resulted in a poor fit of observed and estimated values, with low r-square (.319) and low nearness index (.369). The logistic fit failed in the second formulation. The third formulation resulted in an unbelievably high MSY with F of 0. The estimate of catchability (q) was also extremely low. The model fit was not robust to changes in model parameters. Given that there is little variation in this time series and it is still relatively short (1997-2012) for a long lived species like Greenland halibut this model was not accepted.

3.6 Estimates of MSY from Catches and resilience

A simple Schaefer model was tested on the Greenland halibut stock offshore in NAFO SA 0 and 1. The minimum data required for this model is a catch time series and a measure of the resilience of the species. Other input parameters that had to be guessed were the carrying capacity, the biomass as a fraction of the carrying capacity at both the beginning and end of the time series, and the growth rate. MSY was estimated to be between 19 000 and 23 000 t. Sensitivity tests showed that the estimation of MSY was heavily dependent on the guess of especially the biomass at the end of the time series and the growth rate.

3.7 Environmental Forcing of the Greenland halibut stock dynamics at West Greenland

In the presentation it was shown that year class strength and abundance in West Greenland halibut (WGHL) may be driven by environmental pulses (of different frequencies):

(i) The variability in the Sea Surface Temperature (SST) in the area of Age 1 drift in the mixing layer is regarded as a system wide variable (a co-factor) for WGHL recruitment and abundance. Different trends in SST means and dispersion are reported and the variability is considered as a key co-factor.

(ii) Evidence for the following relationships (p<0.05) is further presented:

(a) Abundance is the inverse of the SST variation considering a lag of 6 years (assumed main of recruitment to the adult population) and can be estimated for short term management planning (5-6 years in advance). Floors in abundance are expected in years 2014 and 2018 and a ceiling in 2017. Two cycles at different levels of abundance were identified.

(b) Age class 1 (considering a lag of 5 years) is both related to overall abundance and showed higher sensitivity for SST minima.

(c) CPUE effort (both means and variability) showed two clear cycles.

(iii) The population system showed several years of memory and it is highly differentiated from a random process (Hurst exponent >0.75) and residuals were –as in several dynamical systems of such nature- auto-correlated (not random).

These relationships were not reported earlier as variability and lags were not considered - due to the use of the Logistic model –or some derivative- which assumes that (a) residuals are random and (b) there is no memory effect in the series (no dependency on preceding values).

The work is still in progress and has not been peer reviewed and is not included in the assessment.

4. Conclusion

Since catches peaked with 18,000 tons in 1992 they have been stable at around 10,000 tons until 2000. Since then catches have gradually increased to 18,696 tons in 2003 and they remained at that level during 2004-2005. The TAC was increased by 5,000 tons in 2006 and catches increased to 24,164 and the TAC has hence been taken. The increase in
catches has been due to increased effort in Div. 0A and Div. 1A. Catches remained at that level in 2007, - 23,416 tons but decreased slightly to 22,380 tons in 2008. Catches increased to 24,805 tons in 2009 and further to 26,934 tons in 2010 due to increased effort in Div. 0B and Div. 1CD. Catches remained at that level in 2012 but increased to 28,062 tons in 2013 mainly due to increased effort inshore in Div. 1D.

Div. 0A+1AB

No R/V survey in 2013

The standardized CPUE index for Div. 0A has been increasing since 2010 and is at the highest level seen since 2004. Standardized catch rates in Div. 1AB has been increasing between 2008 and 2011 but declined in 2012 and 2013 but it is still above the level seen in 2002-2009. The combined Div. 0A+1AB standardized CPUE series has been stable since 2002.

Standardized CPUE for Gill nets has been stable since 2009.

Length frequencies in the fisheries in Div 0A and Div. 1AB have been stable in recent years.

Div 0B+1C-F.

The biomass in Div. 1CD increased between 2003 and 2005, decreased slightly during 2006-2007 and then increased to a record high level in 2008. The biomass decreased in 2009 but increased again in 2010 to a level a little above the average for the time series and the biomass increased further in 2011 to the third highest level in the time series. The biomass decreased in 2012 to the lowest level seen since 2000. No data from 2013.

Estimated total trowable biomass of Greenland halibut in the offshore areas estimated in the Greenland shrimp survey has during 2005-2013 fluctuated between 49,779 and 25,644 tons estimated in 2012. The 2013 estimate was 39,383 tons.

Division 0B was surveyed in 2013. Previous surveys were conducted in 2000, 2001 and 2011, respectively. Total estimated biomass and abundance were 57,765 tons and 5.60x10^7, respectively. Biomass had decreased compared to previous two surveys and was back at the level seen in 2000 and the abundance was lower than in 2000. Biomass and abundance were reduced in all strata compared to 2011.

The offshore recruitment (age one) has been rather stable between 2003 and 2010. The recruitment increased to the highest level in the time series in 2011 but decrease to lowest level seen since 1997 (1996 year-class) in 2012 to increase again to the 3. largest estimate in the times series in 2013.

Standardized CPUE rates in Div. 1CD decreased between 2009 and 2010 but increased again in 2011 and further in 2012 and 2013 to the highest level seen since 1990, while the CPUE decreased in 2012 in Div. 0B to the level seen in 2003-2004 but increased slightly in 2013. The combined Div. 0B+1CD standardized CPUE series has been stable in the period 1990-2004. The CPUE gradually increased to peak in 2009. CPUE decreased slightly between 2009 and 2010 to increase again in 2011, it decreased in 2012 to increase again in 2013 and the estimate is higher than the estimates from 1990-2004.

The standardized CPUE for gill net in Div. 0B has been increasing since 2007 and was in 2013 at the highest level in the time series.

Length compositions in the commercial catches in Div. 0B + 1CD have been stable in recent years.

A standardized CPUE index for all trawlers fishing in SA 0+1 has been increasing between 2002 and 2006 and has been fluctuating at a high level since then. The 2013 estimate was the third largest seen since 1990.
5. Biological reference points

Yield per recruit analysis or other age-based methods are not available, for estimating biological reference points.

There is no accepted analytical model so quantitative estimation of reference points is not possible. SC has recommended that a proxy of $B_{\text{lim}}$ should be estimated based on the survey indexes that are used as the primary basis for advice for this stock.

A preliminary proxy for $B_{\text{lim}}$ was set as 30% of the mean of survey biomass for 1997-2012 in Div. 1CD, the mean of 7 surveys in the southern part of Div. 0A conducted during 1999-2012 and a combined proxy for Div. 0A+1CD, respectively (Fig. 14, Fig. 15 and Fig 16).

$B_{\text{msy}}$ is not known for this stock. If it is assumed that the stock is at or close to $B_{\text{msy}}$ the $B_{\text{lim}}$ should according to Report of the NAFO Study Group on Limit Reference Points Lorient, France, 15-20 April, 2004 (SCS 04/12) be set at 30% of $B_{\text{msy}}$. If the stock increases $B_{\text{lim}}$ should be increased accordingly.

\(\text{c}^a\) Excluding 7603 tons reported by error
\(\text{c}^b\) Reported to the Greenland Fisheries License Control Authority. Statlant 21A data from Div. ICD from Greenland during 2004-2007 include double reported catches.
\(\text{c}^c\) Offshore catches
\(\text{c}^d\) Including 2 tons taken in an experimental fishery
\(\text{c}^e\) Spanish research fishery
\(\text{c}^f\) Includes 131 tons taken in Spanish research fishery
\(\text{c}^g\) Excludes 1366 tons reported from Div. 1A by error
Fig. 1. Catches in SA0 and Div. 1A offshore + Div. 1B-1F and recommended TAC. For TAC before 1995 see text.

Fig. 2a. Biomass index with S.E. from the Greenland deep sea survey in Div. 1CD. No data from 2013.
Fig. 2b. Abundance with S.E. from the Greenland deep sea survey in 1CD. No data from 2013.

Fig. 2c. Mean catch per km$^2$ swept with S.E. in the Greenland deep sea survey in Div. 1CD. No data from 2013.

Fig. 2d. Length distribution in Div. 1D in 2011-2013.
Fig. 2e. Biomass estimates from various surveys in SA 0 and 1. Survey estimates from Div. 0A does not include surveys in the northern part in 2004, 2010 and 2012. No survey in 2013. Note that the survey in Div. 0A in 2006 had incomplete coverage (see text).

Fig. 2f. Biomass estimates for Greenland halibut in Div. 0A (South) with SE and trendline. No survey in 2013.
Fig. 2g. Abundance (right) estimates for Greenland halibut in Div. 0A (South) with SE and trendline. No survey in 2013.

Fig. 2h. Mean catch per tow (with SE for most recent years and linear trend line) for Greenland halibut in Division 0A-South. No survey in 2013.

Fig. 2i. Mean abundance per tow (with SE for most recent years and linear trend line) for Greenland halibut in Division 0A-South. No survey in 2013.
Fig. 2j. Abundance at length for the Greenland halibut in NAFO Division 0A-South, 2004 to 2012 (weighted by stratum area). Includes data from large set. No survey in 2013.

Fig. 2k. Abundance at length for the Greenland halibut in NAFO Division 0A-North, 2004, 2010 and 2012 (weighted by stratum area). No survey in 2013.
Fig. 2 l. Biomass estimates from Div. 0B with S.E. by year.

Fig. 2 m. Over all length distribution weighted by area by year.
Fig. 2n. Biomass index from the Greenland shrimp survey by most important Divisions and in total offshore (including 1C-1F, which have little biomass).

Fig. 3. Abundance of age-one Greenland halibut in the entire area covered by the Greenland shrimp survey including inshore Disko Bay and Div. 1AN (North of 70°37.5’ N) adjusted for change in survey gear in 2005.
Fig 4. Number of one-year of Greenland halibut by division and year.
Fig. 5. Length distribution from the fishery in Subarea 0 in 2010-2012 in per mill., 2 cm groups. No data from the trawl fishery in Div. 0A in 2012. No data from 2013.
Fig. 6. Length distribution in the Russian trawl fishery in Div. 1A in 2011 and 2013 in percent, 2-cm groups. No data from 2012.

Fig. 7. Length distribution in the Greenland trawl fishery in Div. 1A in 2011-2013 in percent, 1-cm groups.
Fig. 8. Length distribution in the Russian trawl fishery in Div. 1D in 2010-2012 in percent, 2-cm groups.

Fig. 9. Length distribution from the Norwegian Trawl fishery in Div. 1D in 2011-2013, and a small Norwegian longline fishery in 2011 in percent, 1-cm groups.
Fig. 10a. Length distribution from the Greenland trawl fishery in Div. 1D in 2013, No data from 2011.

Fig. 10b. Length distribution from the Greenland inshore longline fishery in Div.
Fig. 11a. Un-standardized CPUE from the trawl fishery in Div. 0A.

Fig. 11b. Un-standardized CPUE from the trawl fishery in Div. 0B.
