WAsP = OBS + ROU + ORO
Obstacles

What is an obstacle?

After Meroney (1977)
**Effects of an obstacle**

Reduction of wind speed in per cent due to shelter by a two-dimensional obstacle of zero porosity. Based on the expressions given by Perera (1981)

---

**Trees and shelter belts**

Porosity
in per cent or as a fraction

- Open > 50%
- Dense > 35%
- Very dense < 35%
- Solid = 0%

www.wasp.dk
Specifying obstacles in WAsP

Obstacles are specified as rectangular boxes relative to the site: by two angles and two radii, their height, depth and porosity.

Obstacle viewed in WAsP
Roughness

Equations!

\[ u(z) = \frac{u_*}{\kappa} \ln \left( \frac{z}{z_0} \right) \]

\[ G = \frac{u_*}{\kappa} \sqrt{\left[ \ln \left( \frac{u_*}{f z_0} \right) - A \right]^2 + B^2} \]
Logarithmic profile

Internal Boundary Layer (IBL)
Orography

Stream lines and turbulence over a hill

Stream lines are compressed => wind speed-up!
Askervein Hill Field Experiment

Mother of all flow-over-hill studies:
The Askervein Hill field experiment
(Benbecula Island, Outer Hebrides, Scotland)

Wind measured on masts along a line across the hill
(mast distance 100 m)

Askervein Hill velocity profile

Orography effects on wind speed profile

- Measurement
  WASP flow model
  -- Other flow model

Vertical profile

Horizontal profile of speed-up
BZ-model: Zooming Polar Grid

Inside the BZ-flow-model of WAsP the orography is represented by a zooming polar grid.

The grid is centered around the point in focus: met-station or wind turbine site.

The resolution is highest close to the point in focus, where high resolution matters.

Effect of a steep hill

*Flow Separation*

Ex.#1: Steep but smooth hill

The flow behaves - to some extent - as if moving over a virtual hill with less steep sides =>

*smaller speed-up than calculated by WAsP*

Ref: N.Wood, "The onset of flow separation in neutral, turbulent flow over hills", Boundary-Layer Meteorology 76, 137-164.
Complex terrain and RIX

Outline

• Accumulation of orographic prediction errors
• WASP basics in complex terrain
  – The similarity principle
• Case study in Portugal
  – Wind speed correlations
  – Flow separation
  – RIX and ∆RIX
  – WASP prediction errors
  – RIX/∆RIX configuration
  – Vertical wind profiles
  – Improving WASP predictions in complex terrain?
Background

Accumulation of orographic prediction errors

- Application procedure
  \[ U_h + (\Delta U_2 + E_2) = U_{pe} \]

- Analysis procedure
  \[ U_{rm} - (\Delta U_1 + E_1) = U_h \]

- Combined procedure, eliminating \( U_A \)
  \[ (U_{rm} - \Delta U_1 + \Delta U_2) + (E_2 - E_1) = U_{pe} \]

- The correct estimation is then made up of
  \[ U_{pm} = U_{rm} - \Delta U_1 + \Delta U_2 \] (perfect prediction)
  \[ U_{pe} = U_{pm} + (E_2 - E_1) \] (prediction error!)
The similarity principle

The predictor and the predicted site should be as similar as possible

- **Topographical setting**
  - Ruggedness index (RIX)
  - Elevation and exposure
  - Distance to significant roughness changes (coastline)
  - Background roughness lengths

- **Climatic conditions**
  - Same regional wind climate (synoptic and meso-scale)
  - General forcing effects
  - Atmospheric stability

This means that the basic input data should also be similar

- **WAsP map**
  - Map size
  - Contour interval
  - Accuracy and detail
  - Roughness classification
  - ...

Case study in northern Portugal
Cross-correlation of wind speeds

The flow behaves – to some extent – as if moving over a virtual hill with less steep slopes than the actual hill => actual speed-up is smaller than calculated by WAsP.

Complex terrain analysis

- **Ruggedness index, RIX**
  - fraction of terrain surface which is steeper than a critical slope $\theta_c$
  - Calculation radius ~ 3.5 km
  - Critical slope $\theta_c \sim 0.3-0.4$
  - Onset of flow separation
  - Performance envelope for WAsP is when $\text{RIX} = 0$

- **Performance indicator, $\Delta\text{RIX}$**
  - $\Delta\text{RIX} = \text{RIX}_{WTG} - \text{RIX}_{MET}$
  - $\Delta\text{RIX} < 0 \Rightarrow$ under-prediction
  - $\Delta\text{RIX} > 0 \Rightarrow$ over-prediction

"This performance indicator provides encouraging results…"
The Ruggedness Index – revisited

- Reanalyses of the Portuguese data set
  - Larger, more detailed and accurate maps (SRTM)
  - Improved RIX calculation (WAsP or ME)
  - More calculation radii: 72 rather than 12
  - RIX configuration corresponds to WAsP BZ-model grid
  - Both the prediction errors and ∆RIX change

- Data analysis and presentation
  - Asymmetry in plot of speed error vs. ∆RIX
    - speed error was defined as $\left( \frac{U_p}{U_m} - 1 \right)$
    - not obvious which trend line(s) to fit…
  - Substitute log($U_p/U_m$) for $(U_p/U_m - 1)$
  - Easier to fit a trend line…?

Maps for RIX calculation and test

- Hand-digitised map
  - 8 by 8 km²
  - 50- and 10-m cont.

- SRTM-derived map
  - 20 km diameter
  - 50-, 10- and 5-m height contours
Wind speed error vs. $\Delta$RIX

![Wind speed error vs. $\Delta$RIX graph]

$\ln(U_p/U_m)$ vs. $\Delta$RIX

![ln($U_p/U_m$) vs. $\Delta$RIX graph]

$U_p = U_m \exp(\alpha \Delta RIX)$

where $\alpha = 1.5$

$R = 3500$ m and $\theta_c = 0.3$
Things to test...

- Wind speed prediction error is (almost) fixed...
  - Number of sectors
  - Modelling parameters
- RIX configuration can be varied easily
  - Original configuration somewhat arbitrary
  - Different calculation radii (3, 3.5, 4, and 5 km)
  - Calculation radius that provides max. RIX?
  - Different critical slopes (0.30, 0.35, 0.40, 0.45)
  - Matrix of $R^2$ (coefficient of determination) for different set-up’s
- Weighting RIX with wind rose frequencies

### Influence of radius and critical slope

<table>
<thead>
<tr>
<th>Radius $R$ [m]</th>

<tr>
<td>5000</td>
<td>0.969</td>
</tr>
</tbody>
</table>

$R^2$ for different values of the calculation radius and critical slope.
Recalculation – best fit values

\[ y = 2.406x \]
\[ R^2 = 0.984 \]

Recalculation – weighted w. wind rose

\[ y = 2.370x \]
\[ R^2 = 0.977 \]

\[ U_p = U_m \exp(\alpha \Delta \text{RIX}) \]
where \( \alpha = 2.4 \)
\( R = 3500 \text{ m and } \theta_c = 0.4 \)

Weighted with wind rose
Vertical profile in complex terrain

Tetouan in northern Morocco, RIX = 16%

<table>
<thead>
<tr>
<th>z</th>

www.wasp.dk
Conclusions

- The similarity principle
  - WASP analysis and application errors tend to cancel out
  - The SP is the most important guiding principle for WASP use
  - WASP inputs (maps) should also be similar, of course
- Ruggedness index RIX and performance indicator ΔRIX
  - Concepts supported by new data and procedures
- Relation between WASP prediction error and ΔRIX
  - Linear relation between log(Up/Um) and ΔRIX
  - Relation not very sensitive to calculation radius R, critical slope θc, or prediction height h
  - ΔRIX weighted with the wind rose does not improve the relation between log(Up/Um) and ΔRIX

Conclusions (cont’d)

- Extension of WASP procedures outside operational envelope
  - Requires two or more (non-similar) met. stations
  - Linear relation between ln(Pp/Pm) and ΔRIX
  - Case study AEP predictions improve significantly
  - Linear fit before extended procedure:
    - AEPp = -0.11 AEPm + 2.42
    - R² = 0.01
  - Linear fit after extended procedure:
    - AEPp = 1.01 AEPm
    - R² = 0.92
- Procedure can be applied with (2...n) met. stations
- Procedure should be tested with other data sets...

The New WAsP flow model

Objective

- Micro-scale flow model better able to handle “steep” slopes
  - current WAsP performs poorly over steep slopes
    (>30%)
- To replace/complement the current WAsP orography and roughness models
- Yet not too heavy computationally
Ressource prediction

- Location of turbines ≠ location of met. Masts
- Different surroundings → different wind climates:
  - Obstacles, orography, roughness

The WAsP approach

Wind climate that would be observed on a flat surface
Requirements

The new flow model must be:

- **Quick:**
  - A few hours on a PC for a predicted wind climate
- **Easy to use:**
  - Needs only limited user intervention
  - User expertise on numerical methods not required
  - Minimal number of user-input parameters
- **Stable**
  - Convergence takes place without extensive fine-tuning

Description of the model

- **Governing equations**
  - RANS equations including Coriolis term, continuity
  - Turbulence closure: variant of $k$-$\varepsilon$ model
  - Formulated in
    - General curvilinear coordinates
    - Strong conservation form
- **Calculation domain**
  - Vertically: entire boundary layer ($\sim 10^9$ km)
  - Horizontally: $\sim 20$ km
  - Terrain-following grid
Example grid

- Horizontally periodic
- Flow driven by geostrophic wind at top
- Lower BC
  - law-of-the-wall
  - or no-slip when testing...

New flow model for complex terrain

START
- RANS equations
  - limited length-scale k-ε turb model
- General curvilinear coordinates

Zero-order equations
  - horizontally homogeneous

First-order equations
  - Fractional step method: ensures P-V coupling

Discretised first-order equations
  - Momentum transport
  - Continuity
  - Turbulent kinetic energy
  - Dissipation of TKE

Complete solution

FINISH
Results: flat terrain

- Comparison of turbulence models:

![Graph showing comparison of turbulence models.]

Results – non-flat terrain

- First-order turbulence equations are not ready yet
- Still debugging first-order momentum solver

- Results presented are for “laminar” flow
  - i.e. a uniform eddy viscosity is provided artificially
  - lower boundary condition: no-slip
- In direction perpendicular to the screen:
  - Grid is uniform, no driving
  - 2D problem solved in 3D
Streamwise velocity

Zero-order solution

First-order solution

Problem with BC

Speed-up

Vertical velocity

Zero-order solution

First-order solution

www.wasp.dk
Final solution

Streamwise velocity

Vertical velocity

• Lean, mean, and, well… "room for improvement" in the accuracy department
• 512 (L) x 64 (H) x 4 (W) grid : calculation takes a few minutes

Work ahead

• Debugging and testing of the first-order momentum solver
  – Newly-discovered error in the upper/lower boundary conditions of the Poisson and projection equations
  – Re-writing terms of the first equation to include previously neglected geometry terms
  – And more...
• Debugging and testing of the turbulence closure
• Test cases, calculations, fine-tuning and analysis
Forest and wind turbines

... is generally a bad combination...

Outline

- How is a forest different?
- Forest model parameters
- Turbine/mast close to forest
- Turbine/mast not so close to forest
How is a forest different 1?

\[ z \rightarrow z - d \]

How is a forest different?

inflection point
How is a forest different?

The roughness sublayer effect

Displacement height $\Rightarrow$ Forest edge effects

Problem areas

www.wasp.dk
How is a forest different?

- Introduction of displacement height – porous surface in tree crown level
  1. Roughness sublayer
  2. Flow effects at forest edge

- Forests are aerodynamically much rougher than for example the sea surface

\[
\begin{align*}
0.5m &< z_{0,\text{forest}} < 2.5m \\
0.01m &< z_{0,\text{agric}} < 0.15m \\
10^{-3}m &< z_{0,\text{sea}} < 10^{-2}m
\end{align*}
\]
Roughness and zero displacement height

Depends on
1. The mean height of the roughness elements (trees)
2. The density of the forest

DENSE
- low roughness
- high zero displacement

SPARSE
- high roughness
- low zero displacement

The roughness sub-layer effect
Forest edge effects

dense

sparse

www.wasp.dk

Forest density 1

How is it parameterised?

Raupach (1992):

\[ \lambda = \frac{bh}{D^2} = \frac{bh}{S} \]

\[ \lambda \approx \frac{LAI}{2} \]

LAI

leaf area index

www.wasp.dk
Forest density 2

Displacement height

Roughness length

Height and wind in roughness sublayer

Forest edge effect

How is forest flow parameterised?

$$\lambda = \frac{bh}{D^2}$$

- $b$: Tree breadth
- $h$: Tree height
- $D$: Distance between trees

www.wasp.dk
What is close?

Close \( x < 20d \)
Not so close \( x > 20d \)

Forest edge effect should be included

Orographic effects of forest edge, mean wind
Turbulent effects of forest edge

\[ \frac{\sigma_u}{u} \]

- high up
- close to forest

Wind turbine not so close to a forest, \( x > 20d \)

- Internal boundary layers
  - \( h_{\text{rough}} \)
  - \( h_{\text{smooth}} \)
IBL structure

\[ \frac{h_i}{z_{02}} = 0.09 \left( \frac{x}{z_{02}} \right)^{0.77} \]  

(Dellwik and Jensen, 2000, WAsP)

---

Wind turbine not so close to a forest, \( x > 20d \)

*How far away from the forest is the forest influence of no consequence?*

---

www.wasp.dk
Scary story – low turbine in small clearing

- high roughness, no effect of clearing
- orographic effect leads to a reduction in wind
- edge effects may cause a very turbulent environment

New project: *Wind Profiles and Forest*

Masts for turbulence and mean wind speed measurements
Use in WAsP

- Estimate $\lambda$
- Calculate $z_0$
- Calculate $d$
- Input $z_0$ in WAsP map
  - effect of high roughness taken into account
  - effect of IBL growth taken into account
- Subtract $d$ from all heights (mast and turbine)

- Turbines in forest do not necessarily “see” a forest.
- Turbines outside a forest are likely to be influenced by the forest if the forest is not very far away (take care at edge!)

The logarithmic profile

[Graph of logarithmic profile]
The logarithmic profile

KAMM/WAsP Methodology
- meso-scale modelling
Numerical Wind Atlas Methodology

- useful when long-term measurement data unavailable
- uses the principle of statistical dynamical downscaling

**large-scale meteorological conditions**

**small-scale meteorological conditions**

Need:
- tool to calculate how atmospheric flow modified by terrain
  - mesoscale model
- information about large-scale meteorological conditions
- information about terrain
  - surface elevation (orography)
  - surface roughness
KAMM – Mesoscale model

Karlsruhe Atmospheric Mesoscale Model
non-hydrostatic, regular horizontal grid, stretched vertical coordinate (terrain following)

Large-scale meteorological conditions

- NCEP/NCAR reanalysis data provides large-scale, long-term atmospheric forcing.
  - 2.5 x 2.5 degree resolution
  - 4 times daily
  - 1948 to present

Calculate profiles of
- geostrophic wind
- potential temperature
at 0, 1500, 3000, 5500 m (1965-1998)
Terrain description

**Orography**
- United States Geological Survey (USGS), GTOPO30 data – approx. 1km resolution.

**Surface roughness**
- USGS Global Land Cover Classification – approx. 1km resolution.
- Land use $\rightarrow$ surface roughness (via look-up table)

**Statistical-dynamical downscaling**
- We could run KAMM using 30 years of 4 times daily data as large-scale forcing conditions
  - $30 \times 365 \times 4 = 43800$ integrations
  - A lot of work! ...and also repetition.
- Instead we select around 100 representative conditions, called wind classes profiles.
- *Statistical-dynamical downscaling*
The WAsP part in KAMM/WAsP

Example:
simulated wind
wind corrected to standard conditions

*flat terrain with homogeneous roughness*

Conclusions

The KAMM / WAsP method has been used to create numerical wind atlases for Egypt.

- 2 large domains cover all of Egypt
  - 7.5 km resolution

- 4 smaller domains cover specific regions of interest in more detail
  - 5 km resolution
  - location specific wind profiles

Conclusions

- colour maps produced are just a graphical “slice” of the data generated by the method.

- .lib files are also generated

- WAsP can then be used to determine local effects
  - orographic speed up
  - roughness change

- Verification shows error to be around 5-10 % on wind speed.
Summary

- Wind Atlas Methodology: industry-standard (rou, oro, obs)
- Complex terrain: RIX, new WAsP
- Forest ($\lambda$)
- KAMM/WAsP (Egypt case)
