Resources Engineering (CERE), 2800 Kongens Lyngby, Denmark.*

The enzyme Carbonic Anhydrase (CA) can accelerate the absorption rate of CO₂ into aqueous solutions by several-fold. It exist in almost all living organisms and catalyses different important processes like CO₂ transport, respiration and the acid-base balances.

A new technology in the field of carbon capture is the application of enzymes for acceleration of typically slow ternary amines or inorganic carbonates. There is a hidden potential to revive currently infeasible amines which have an interesting low energy consumption for regeneration but too slow kinetics for viable CO₂ capture.

The aim of this work is to discuss the measurements of kinetic properties for CA promoted CO₂ capture solvent systems. The development of a rate-based model for enzymes will be discussed showing the principles of implementation and the results on using a well-known ternary amine for CO₂ capture. Conclusions will be drawn revealing basic unexpected process conditions which are beneficial to enzyme promoted amines like water presence, temperatures, and similar basic variables.
