ABSTRACT

The present study describes the growth of the very well-known probiotic bacterium *Lactobacillus acidophilus* NCFM on different carbohydrates. Furthermore, recombinant production of putative moonlighting proteins elongation factor G and pyruvate kinase from this bacterium is described. For further and detailed interpretation of the data presented here, please see the research article “Mucin- and carbohydrate-stimulated adhesion and subproteome changes of the probiotic bacterium *Lactobacillus acidophilus* NCFM” (Celebioglu et al., 2017) [1].

### Value of the data

- Growth data presented here shows growth potential of the probiotic bacterium *Lactobacillus acidophilus* NCFM on different carbon sources.
- The growth data may be used by researchers to understand the ability of the bacterium to grow on different carbon sources.
- Data regarding recombinant production of elongation factor G and pyruvate kinase from *Lactobacillus acidophilus* NCFM may be used by researchers to apply the same procedure.
- Data shown here and in Ref. [1] are useful for the researchers who are working on gut microbiota, probiotic bacteria, carbohydrate-microbe interactions, and moonlighting proteins.

### 1. Data

The extensively used probiotic bacterium *Lactobacillus acidophilus* NCFM was grown on nine different carbohydrates including growth on glucose supplemented with mucin (Fig. 1). The putative moonlighting proteins elongation factor G and pyruvate kinase also identified from this bacterium by differential proteomics [1] were recombinantly produced using the primers shown in Table 1 and purified by his-tag affinity chromatography. The purified proteins were analysed by SDS-PAGE (Fig. 2). Table 2 reports on the mass spectrometric identiﬁcation of the two puriﬁed proteins without any identiﬁcation of *E. coli* proteins.

### 2. Experimental design, materials and methods

*L. acidophilus* NCFM (NCFM) (1.50 × 10¹⁰ CFU/g DuPont, USA Inc., Madison, US) was grown aerobically without shaking at 37 °C in batch cultures (50 mL) in semisynthetic lactic acid bacteria medium (LABSEM) [2] containing 1% FOS (Sigma-Aldrich); GOS; polydextrose (both DuPont); melibiose (Fluka); lactulose (Sigma-Aldrich); cellobiose (Sigma-Aldrich); isomaltulose (palatinose; Sigma-Aldrich); or trehalose (Sigma-Aldrich); and the reference glucose (Sigma-Aldrich). Porcine gastric mucin to 0.1% (Sigma-Aldrich) was included in cultures with 1% glucose. The bacterium was sub-
cultured for three cycles in LABSEM and growth was monitored at early stationary phase (24 h) by measuring absorbance at 600 nm.

Gene-specific primers for \textit{lba0289} (elongation factor G, EF-G) and \textit{lba0957} (pyruvate kinase, PK) with extra 15 bp complementary to the pET28a(+) vector linearized with BamHI and NdeI (Table 1) were designed using CLC Main Workbench software (Qiagen), primer blasted (NCBI), and used to amplify genes by PCR. Cloning was performed with In-Fusion Cloning kit (Clontech) per the user manual. The resulting plasmids were transformed into competent \textit{E. coli} DH5α and positive colonies were selected using kanamycin LB agars. Inserted genes were confirmed by sequencing (GATC Biotech). Soluble recombinant proteins were obtained in \textit{E. coli} BL21 (DE3) induced with 0.1 mM isopropyl-\(\beta\)-D-thiogalactoside. Cells were disrupted using a high-pressure cell homogenizer (Stanstead), followed by centrifugation (10,000 \(\times\) g, 20 min). Recombinant proteins (rEF-G and rPK) were purified (HisPur™ Cobalt Purification Kit; Thermo Scientific) according to the manufacturer’s instructions and verified by SDS-PAGE (Fig. 2) [3].

![Fig. 1. In vitro evaluation of growth of \textit{Lactobacillus acidophilus} NCFM (early stationary phase, 24 h) on different carbon sources (1%) or supplemented with mucin (0.1%). Asterisk (*) indicates that the difference in growth of the bacteria are statistically significant compared to growth on glucose (\(p \leq 0.05\)).](image-url)
Bands corresponding to elutions in Fig. 2 were excised manually, subjected to in-gel degradation by trypsin and MS protein identification. Briefly, gel pieces were washed with 40% ethanol (200 µL, 10 min) followed by acetonitrile (ACN) (50 µL), reduced with DTT (10 mM in 100 mM NH₄HCO) and alkylated with iodoacetamide (55 mM in 100 mM NH₄HCO), incubated with 12.5 ng/mL trypsin (Promega) in 10 mM ammonium bicarbonate (5 µL, on ice, 45 min), added 10 mM ammonium bicarbonate (10 µL), and incubated (37 °C, overnight). Supernatant (1 µL) was applied onto an Anchor Chip target (Bruker-Daltonics), added matrix (1 µL 0.5 mg/mL CHCA in 90% ACN, 0.1% TFA) and washed (2 µL 0.02% TFA). MS spectra were obtained using an Ultraflex II MALDI-TOF MS mass spectrometer (Bruker-Daltonics) in auto-mode with Flex Control v3.0 (Bruker-Daltonics) and processed by Flex Analysis v3.0 (Bruker-Daltonics). Protein sequences were searched against the NCBIprot database (ver. 20170215) or SwissProt for bacteria using the MASCOT 2.0 software (http://www.matrixscience.com) integrated with BioTools v3.1 (Bruker-Daltonics). Protein identifications by Peptide Mass Fingerprinting (PMF) were confirmed with a MASCOT score of 80 (60 for SwissProt), p ≤ 0.05 and a minimum of six matched peptides.

### Table 2

MALDI-TOF MS results of recombinantly produced elongation factor G and pyruvate kinase of *Lactobacillus acidophilus* NCFM. No *E. coli* proteins were identified.
