Citation (APA):
sound to assess aortic stenosis and PET/computed tomography (CT) with 18F- NaF to assess calcification severity. Thereafter, 8 animals were subsequently treated with local delivery of a mixture containing 500 μg zolendronate that was delivered on the cusps of the aortic valve, by a dedicated balloon catheter. A placebo mixture was administered on the rest 8 animals (control group). At 28 days all animals underwent a follow-up cardiac imaging with PET-CT 18F-NaF. The progression of calcification was assessed by calculating the difference in SUVmax, SUVmean, TBRnxmax and TBRmean at baseline and at follow up both for AV and ascending aorta (AA). After the second PET/CT examination all animals were sacrificed and all aortic valves were collected and analyzed by histology.

Results: At baseline, all animals developed aortic valve stenosis with severe calcification. No differences regarding AVA were recorded between both groups. (21.37±1.76 vs 21.98±3.12, p<0.53). In all animals the local delivery of zolendronate and placebo mixtures was successful and uncomplicated. A total of 48 cusps were histologically examined. The cusps treated with zolendronate had significantly lower expression of calcium content compared to the cusps of the placebo group (16.40±0.90 vs 24.88±1.90% of the area, p<0.0001), whereas the ascending aortas of both groups showed similar expression of calcium content (23.58±4.43 vs 23.12±5.05% of the area, p=0.78). Regarding PET/CT analysis, in the zolendronate group, TBRmean and TBRmax at the level of AA showed a significant increase of calcification during follow up (1.310±11.1 versus 1.63±1.84, p<0.001 and 1.42±0.11 versus 1.64±0.20, p<0.001). In the same group TBRmean and TBRmax at the level of AV did not show any significant change in calcification during the same period (1.20±0.12 versus 1.17±0.78, p=0.29 and 1.30±0.33 versus 1.40±0.67, p=0.08). Interestingly TBRmean showed a regression of calcification at the level of AV compared to AA (-0.34±0.07 versus 0.30±1.1, p<0.01). Compared with aortic valve calcification in the absence of local catheter-based delivery of zolendronic acid is feasible without evident short-term complications. The potential clinical implications should be confirmed in human studies.

Macrophage-derived osteopontin is fragmented by MMP-9 to hinder angiogenesis in the post-myocardial infarction left ventricle

S. Holm Nielsen1, E.R. Flynn2, M. Lindsey2. 1Technical University of Denmark, Department of Biotechnology and Biomedicine, Lyngby, Denmark; 2The University of Mississippi Medical Center, Jackson, United States of America

Background/Introduction: Extracellular matrix (ECM) turnover is a key event during remodeling of the left ventricle (LV) following myocardial infarction (MI). Turnover includes ECM degradation of existing ECM to remove necrotic myocytes and synthesis to produce new ECM to form the scar tissue. Matrix metalloproteinases (MMPs) are expressed post-MI, and MMP-9 has a strong link to post-MI LV dysfunction. The ECM protein osteopontin (OPN) increases post-MI, and we previously identified by mass spectrometry a novel MMP-9 cleavage site of OPN between amino acids 151 and 152. In vitro, peptides both upstream and downstream of the cleavage site increased cardiac fibroblast proliferation without affecting proliferation of myocytes.

Purpose: The aim was to determine the biological function of the MMP-9 generated OPN fragment in vivo post-MI, using full length and cleavage-site specific OPN antibodies.

Methods: C57Bl/6J wild type (WT) and MMP-9 null mice (3–6 months old) were used for coronary artery ligation and examined at days 0, 1, 3, 5, and 7 post-MI. All animal procedures were approved by the Institutional Animal Care and Use Committee at a University Medical Center in accordance with the Guide for the Care and Use of Laboratory Animals. Immunoblotting and immunohistochemistry were used to quantify full-length and OPN fragments. In vivo angiogenesis assay was performed using HUVECs to compare spanning OPN fragment peptide to fragment peptides upstream and downstream of the cleavage site.

Results: In vivo, both full length OPN and the cleaved OPN fragment increased in the LV infarct in WT from days 1 to 5, with a peak elevation at day 5 post-MI. Compared to WT, post-MI MMP-9 null LV showed a surprising increase in cleavage product, indicating that MMP-9 may further degrade OPN with prolonged exposure. This was confirmed by in vitro cleavage assay. By immunohistochemistry, we identified myocytes as the main cellular source of OPN in the absence of MI. Post-MI, macrophages were robustly positive for both full length OPN and the cleaved fragment. An angiogenesis assay was performed to further elucidate the biological function of MMP-9 generated OPN fragments. While total tumor formation was not altered, the OPN spanning peptide increased total branching and segment length, effects that were abolished when peptides upstream or downstream of the cleavage site were used.

Conclusions: Our results demonstrated that in vivo post-MI, MMP-9 increased OPN, which was processed by a novel MMP-9 cleavage product, a result of macrophage infiltration, and in vitro cleavage peptides impaired angiogenesis quality.

Mitochondrial calpains mediate SIRT3-dependent cardiac dysfunction in LPS-induced endotoxemia

K. Koentges1, M.C. Cimolai1, K. Pelll1, S. Alvarez2, M.M. Hoffmann3, C. Bode1, H. Bugger1. 1University Heart Center Freiburg - Bad Krozingen, Freiburg, Germany; 2University of Buenos Aires, Institute of Biochemistry and Molecular Medicine, School of Pharmacy and Biochemistry, Buenos Aires, Argentina; 3University of Freiburg, Department of Clinical Chemistry, Freiburg University Hospital, Freiburg, Germany

Septic patients may have myocardial dysfunction, likely related to concomitant mitochondrial dysfunction in the heart. In the present study, we hypothesized that myocardial dysfunction was caused by mitochondrial ATP synthase, which may increase activation of mitochondrial calpain activity and thereby contribute to mitochondrial and contractile dysfunction in sepsis. In isolated working hearts, 6 hours of LPS treatment resulted in a decrease in cardiac power (-22%), palmitate oxidation (-33%) and cardiac efficiency (-34%), accompanied by a 57% decrease of the mitochondrial fraction NAD+/NADH ratio compared to non-treated mice (all p<0.05). PARP1 deletion in relaxin expressed cardiac myocytes resulted in a significant increase of cardiac contractile function in LPS-treated WT mice (-22%), but not in LPS-treated PARP1−/− mice. Thus, LPS-induced endotoxemia causes cardiac dysfunction by PARP1-mediated NAD+ depletion and subsequent impairment in SIRT3 activity, which may increase activation of mitochondrial calpains.

Hydrogen gas inhalation improves survival in rats with lethal haemorrhagic shock

T. Matsuoka1, M. Suzuki1, M. Sano2, K. Hayashida1, T. Tamura1, H. Homma1, F. Kufuka3, J. Sasaki1. 1Keio University School of Medicine, Department of Emergency and Critical Care Medicine, Tokyo, Japan; 2Keio University School of Medicine, Department of Cardiology, Tokyo, Japan

Background: Haemorrhagic shock is a major perioperative complication and is the primary cause of death following trauma among both civilians and military personnel. Immediate identification of patients who are at high risk for haemorrhagic shock and effective definitive treatment is applied, affects their probability of survival. Hydrogen (H2) gas has potential as an antioxidant. We investigated whether H2 gas inhalation affects the tolerance to haemorrhagic shock and improves survival.

Methods: Thirty male Sprague-Dawley rats were anesthetised and subjected to haemorrhagic shock by withdrawing blood until the mean arterial blood pressure reached 30–35 mmHg. After 60 minutes of shock, rats were resuscitated with normal saline measuring four times the volume of shed blood over 15 minutes. The rats were assigned to one of three groups: the early H2 group (the gas mixture [1.3% H2, 26% O2, and 72.7% N2] was inhaled since the initiation of haemorrhagic shock, N=10), late H2 group (the gas mixture was inhaled since the initiation of fluid resuscitation, N=10), and control group (control gas mixture [26% O2 and 74% N2] was inhaled since the initiation of haemorrhagic shock, N=10). Inhalation of the specified gas mixture continued for 2 hours after fluid resuscitation. The survival rate at 6 hours after fluid resuscitation and haemodynamic parameters were evaluated.

Results: The survival rate was 30% in the control group, 80% in the early H2 group, and 50% in the late H2 group (p=0.036). The volume of blood removed to induce shock tended to be the largest in the early H2 group (control vs. early H2 vs. late H2 groups: 2.4±0.12 vs. 2.76±0.11 vs. 2.44±0.11 ml/100 g; p=0.082). Fluid resuscitation almost completely restored the blood pressure in the early H2 group, whereas it failed to fully restore the blood pressure in the late H2 and control groups.
