Manganese-Catalyzed Cross Coupling of Aryl Halides and Grignard Reagents by a Radical Mechanism

Giuseppe Antonacci,[a] Andreas Ahlburg,[a] Peter Fristrup,[a] Per-Ola Norrby,[b,c] and Robert Madsen*[a]

Abstract: The substrate scope and the mechanism have been investigated for the MnCl₂-catalyzed cross coupling reaction between aryl halides and Grignard reagents. The transformation proceeds rapidly and in good yield when the aryl halide is a chloride containing a cyano or an ester group in the para position or a cyano group in the ortho position. A range of other substituents gave no conversion of the aryl halide or led to the formation of side products. A broader scope was observed for the Grignard reagents where a variety of alkyl- and arylmagnesium chlorides participated in the coupling. Two radical clock experiments were performed which in both cases succeeded in trapping an intermediate aryl radical. The cross coupling is therefore believed to proceed by a S₄N₃ mechanism, where a triorganomanganate complex serves as the most likely nucleophile and single electron donor. Other mechanistic scenarios were excluded based on the substrate scope of the aryl halide.

Introduction

The palladium-catalyzed cross coupling reaction has been one of the most important discoveries in organic chemistry over the past 50 years.[1] The reaction has had a tremendous impact on the pharmaceutical industry where it accounts for about 10% of all reactions used in the synthesis of drug candidates.[2] The reaction, however, suffers from one major drawback which is the use of the metal palladium. This metal does not occur naturally in the human body and all palladium compounds are considered toxic.[3] Furthermore, palladium is a precious metal with a low annual production. This has prompted a thorough search for alternative catalysts where nickel complexes have been extensively investigated,[4] but are more toxic than the palladium counterparts.[5] Recently, copper,[6] iron[7] and cobalt[8] complexes have gained much attention, but often high catalyst loadings are required. As a result, there is still a demand for effective, cheap and non-toxic catalysts for the cross coupling reaction.

This has inspired research into manganese catalysts since manganese is one of the cheapest metals and is also present in all living organisms. Although, the general application of manganese in homogeneous catalysis is rapidly increasing,[9] the metal has still only found limited applications for the cross coupling reaction. To date, only four publications describe the manganese-catalyzed coupling between aryl/alkenyl halides and Grignard reagents where MnCl₂ is used as the catalyst in all cases.[10-13] This includes the coupling of activated aryl halides,[9] reactive heterocyclic chlorides[10] and arylmagnesium hexafluoride[11] with both alkyl- and arylmagnesium halides. No information is provided about the mechanism of these manganese-catalyzed reactions.

We envisaged that the scope of the MnCl₂-catalyzed coupling between aryl halides and Grignard reagents could be expanded, possibly by gaining an understanding of the reaction mechanism. Some of us have previously studied the reactivity of Grignard reagents[14] and investigated the mechanism of the iron-catalyzed cross coupling[15] and the Barbier allylation.[16] We decided to use the MnCl₂-catalyzed cross coupling between activated aryl halides and aryl/alkyl Grignard reagents as a starting point for our investigation.[9] In this transformation, o-chlorobenzonitrile undergoes a successful reaction with the organomagnesium halides in THF solution with 10% of the catalyst.[9] In addition, both o- and p-chlorobenzaldehyde N-butylimine can be coupled with the Grignard reagents under the same conditions.[9] However, this is a very narrow range of substrates and it would be interesting to exploit the transformation with a broader array of aryl halides. Herein, we describe the substrate scope and limitations for the manganese-catalyzed cross coupling of aryl halides with Grignard reagents and elucidate part of the reaction mechanism.

Results and Discussion

The studies began by investigating the reaction between cyclohexylmagnesium chloride and various para-substituted halobenzenes (Table 1). The coupling afforded a 94% yield with p-chlorobenzoazinetrile (entry 1) while methyl p-chlorobenzoate gave 65% yield (entry 2). The transformation was performed in THF since the coupling with p-chlorobenzoconitrile gave a higher yield in this solvent than in diethyl ether, dioxane, DME or toluene. In addition, the best results with this substrate were obtained with MnCl₂ as the catalyst while a lower yield was achieved with MnBr₂ and no coupling occurred with MnF₂, MnI₂ or in the absence of a manganese salt. The use of additives such as LiCl and MgBr₂ also led to lower yields. MnCl₂ is not soluble in THF, but dissolves upon addition of the Grignard reagents to afford a brown solution. Chloride appears to be the preferred leaving group since only a 43% yield was obtained.

[a] Isolated yield.

Attempts to extend the coupling to a variety of other para-substituted halobenzenes were not successful. No reaction was observed when \( \text{p-fluorobenzonitrile} \) and \( \text{p-chlorobenzonitrile} \) were mixed with the Grignard reagent under the optimized conditions (entries 5 and 6) which are important observations for understanding the mechanism of the coupling. The trifluoromethyl and the cyano group are both electron-withdrawing groups with Hammett constants around 0.6[15] and the vast difference in reactivity between these groups indicates that an oxidative addition to the aryl chloride is not part of the reaction pathway. The fact that the chloro substrate reacts well with the Grignard reagent while the fluoro compound is unreactive shows that the transformation does not proceed by a \( \text{S}_{\text{N}}\text{Ar} \) mechanism through an intermediate Meisenheimer adduct with the addition as the rate-determining step.

A number of other para-substituted halobenzenes were also unreactive or led to side reactions. \( \text{p-Chloronitrobenzene} \) reacted with the Grignard reagent at the nitro group (entry 7) which is a known transformation for organomagnesium halides[15] whereas no reaction was observed with \( \text{N,N-dimethyl p-bromobenzamide} \) (entry 8). \( \text{p-Chlorobenzoaldehyde} \) and \( \text{-acetonophene} \) underwent addition to the carbonyl group while chlorobenzenes with a methyl, phenyl, bromo, methoxy or methylylthio substituent in the \( \text{para} \) position did not react with cyclohexylmagnesium chloride (results not shown). The meta-substituted substrate, \( \text{m-chlorobenzonitrile} \), did not react either under the optimized conditions.

The coupling could be extended to other Grignard reagents as shown in the reaction with \( \text{p-chlorobenzonitrile} \) (Table 2, entries 1 – 7). The transformation gave moderate to good yields with a variety of different aryl- and alkylmagnesium halides. The corresponding \( \text{o-chlorobenzonitrile} \) underwent a similar coupling with the Grignard reagents and the yields were close to the results obtained for the \( \text{para} \) substrate (Table 2, entries 8 – 12). Both substrates were also reacted with allylmagnesium chloride, but the results were difficult to reproduce although the substitution product was obtained in moderate yields in some cases. In addition, the different Grignard reagents were reacted with \( \text{p-chlorobenzotrifluoride} \), \( \text{p-chloroanisole} \) and \( \text{m-chlorobenzonitrile} \), but no conversion of these chlorobenzenes was observed which is in line with the results in Table 1. The reaction between methyl \( \text{p-chlorobenzoate} \) and phenylmagnesium chloride gave substitution at the ester group and no reaction occurred with the halide. The same substitution to produce the ketone was observed when \( \text{p-chlorophenylmagnesium bromide} \), \( \text{p-methoxyphenylmagnesium bromide} \) and allylmagnesium chloride were reacted with methyl \( \text{p-chlorobenzoate} \).

Table 2. Coupling with \( \text{p-} \) and \( \text{o-chlorobenzonitrile} \).

[a] Isolated yield. [b] Yield based on NMR since the isolated product could not be obtained completely pure.

The influence of the temperature and the reaction time was investigated with \( \text{p-chlorobenzonitrile} \) and phenylmagnesium chloride. No reaction occurred at -12 °C while at 0 °C about 5% of the product was formed after 2 hours. At 6 °C almost 80% of the chloronitrile was consumed after only 1 minute followed by very little further consumption of the starting material over the next 30 min. At room temperature the coupling essentially went...
to completion within 1 minute after which time the solvent was refluxing due to the exothermic nature of the reaction.

To further probe the influence of the Grignard reagent, a competition experiment was set up in which \(p\)-chlorobenzonitrile was allowed to react with a mixture of phenyl- and cyclohexylmagnesium chloride (i.e., a contest between the reactions in Table 1, entry 1 and Table 2, entry 1). This resulted in immediate formation of \(p\)-cyclohexylbenzonitrile and very little of \(p\)-phenylbenzonitrile which shows that the most nucleophilic Grignard reagent is also the most reactive. An additional competition experiment was set up in which cyclohexylmagnesium chloride was allowed to react with a mixture of \(p\)-chlorobenzonitrile and methyl \(p\)-chlorobenzoate (i.e., a contest between the reactions in entry 1 and 2 in Table 1). In this case, the two substitution products were formed in equal amounts and the \(p\)-cyano and the \(p\)-methyl ester substituents therefore display a similar influence on the reactivity of the aryl halide.

![Figure 1. Substrates investigated for the Hammett study.](image)

A Hammett study was also considered because it may provide information about the nature of the intermediate species in the coupling.\[^{17}\] Since the reaction gives the best results with \(\alpha\)- and \(p\)-chlorobenzonitrile, differently substituted analogs of these were investigated as possible substrates for the kinetic study (Figure 1 and Scheme 1). Unfortunately, analogs 1 – 4 all led to mixtures of several products when reacted with cyclohexylmagnesium chloride. Only with methyl substituted analogs 5 – 7 was it possible to obtain one coupling product 8 – 10 upon reaction with the cyclohexyl Grignard reagent and MnCl\(_2\) (Scheme 1). The yields ranged from 88% and 81% with 5 and 7 to 62% with 6. It is noteworthy that compound 6 can be coupled at all since the halide and the cyano group are positioned \(meta\) to each other.

![Scheme 1. Coupling of chloromethylbenzonitriles.](image)

These results show that the substrate scope of the cross coupling is limited under the present conditions. However, the transformation is still very fast with a narrow range of \(ortho\)- and \(para\)-substituted aryl halides and the mechanism must therefore involve a pathway where these substituents are essential. As mentioned above, the reaction is not operating by a classical \(S_NAr\) route or through an oxidative addition pathway as known for the corresponding palladium- and nickel-catalyzed reactions. This raises the question whether a radical pathway is involved, i.e., a \(S_NR_1\) mechanism.\[^{18}\] Alkali metal enolates and a few other carbanions have previously been reacted with halobenzenes through a \(S_NR_1\) pathway,\[^{18}\] but whether Grignard reagents are able to react with aryl radicals is still a matter of debate.\[^{19}\]

Several experiments were therefore conducted in order to trap an intermediate aryl radical. First, the reaction between \(p\)-chlorobenzonitrile and cyclohexylmagnesium chloride was repeated in the presence of cyclohexa-1,4-diene in an attempt to dehalogenate the aryl chloride. However, the coupling still proceeded smoothly under these conditions and gave \(p\)-cyclohexylbenzonitrile as the only product. Then, a radical clock experiment was designed in which allyl ether 13 and the corresponding but-3-enyl compound 14 were reacted with cyclohexyl Grignard and MnCl\(_2\) (Scheme 2). The two olefinic chlorobenzonitriles were prepared by allylation from the corresponding phenol 11 and benzyl bromide 12. Compound 14 could not be obtained completely pure, but contained about 30% of a byproduct where the olefin had migrated. The reaction with cyclohexylmagnesium chloride gave in both cases a mixture of several compounds, but the main products arose from cyclization with the olefin and addition to the nitrile. The cyclization products 15 and 16 were isolated in 9% and 7% yield, respectively. Only very small amounts (1 – 2%) were observed by GCMS from the direct cross coupling between the aryl halide and the Grignard reagent, but the products could not be isolated or further quantified.

![Scheme 2. Radical clock experiments.](image)
The mechanistic proposal in Scheme 3 should be compared with the recently published cross coupling reaction between aryl iodides/bromides and aryl Grignard reagents in the absence of a catalyst.\[25\] This reaction was performed in toluene at 110 °C for 24 h and allowed for coupling of ether and alkyl substituted aryl moieties.\[25\] The mechanism was subsequently investigated and a radical clock experiment failed to produce the cyclization product from an aryl radical.\[26\] DFT calculations suggested a pathway where the starting aryl halide Ar–X is converted by SET into [Ar–X]⁻ which reacts with Ar'–MgBr to furnish a magnesium ion-radical cage [Ar–Ar'MgBr].\[19\] The latter is transformed into a ArMgAr' radical anion from which [Ar–Ar']⁻ is formed following by SET to Ar–X.\[19\]

Conclusions

In summary, we have managed to exclude several commonly proposed catalytic cycles for the manganese-assisted coupling of Grignard reagents with aryl chlorides, and by inference, limited the mechanistic possibilities to one plausible reaction mechanism, $S_{Nn1}$. In line with this mechanism, a narrow aryl halide scope is observed, where only substituents allowing a single electron reduction followed by a facile halide dissociation give coupling. The proposed radical intermediate can be trapped by an internal radical clock substituent, but will prefer coupling with the Grignard reagent over base-stable intermolecular radical traps like cyclohexadiene. Substrates that will react directly with Grignard reagents, such as nitro-aromatics, ketones and aryl iodides, are not competent coupling partners. On the Grignard side, the scope is wider and allows for coupling of a variety of alkyl and arylmagnesium halides.

Experimental Section

General Information: All solvents were of HPLC grade and were not further purified. Gas chromatography was performed on a Shimadzu GCMS-QP2010S instrument fitted with an Equity 5, 30 m × 0.25 mm × 0.25 μm column. Flash column chromatography separations were performed on silica gel 60 (40–63 μm). NMR spectra were recorded on a Bruker Ascend 400 spectrometer. Chemical shifts were measured relative to the signals of residual CHCl₃ (δ = 7.26 ppm) and CDClear (δ = 77.16 ppm). HRMS measurements were made using ESI with TOF detection. All Grignard reagents were obtained from commercial suppliers and titrated with a 0.06 M solution of i₂ in Et₂O to determine the concentration: cyclohexylmagnesium chloride (1.6 M in Et₂O), phenylmagnesium bromide (0.9 M in THF), p-methoxyphenylmagnesium bromide (0.3 M in THF), p-chlorophenylmagnesium bromide (0.5 M in Et₂O), p-tolylmagnesium bromide (0.9 M in THF), n-butylmagnesium chloride (1.8 M in THF), n-butylmagnesium chloride (1.8 M in THF) and isopropylmagnesium bromide (0.8 M in THF).

General Procedure for Cross Coupling: A dry three-neck Schlenk tube was equipped with a stir bar and a nitrogen inlet. The flask was flushed with nitrogen and charged with MnCl₂ (25 mg, 0.2 mmol) and dry THF (6 mL). The mixture was stirred for about 10 min to completely dissolve MnCl₂ followed by addition of the aryl halide (2 mmol) and cooling to 0 °C in an ice bath. A solution of the Grignard reagent (4 mmol) was added dropwise over 5 min and the ice bath was removed. The mixture was stirred for 1 h at ambient temperature. Decane (0.4 mL, 2 mmol) was added.

Scheme 3. Proposed mechanism for manganese-catalyzed cross coupling.

These results prompted us to propose the $S_{Nn1}$ mechanism in Scheme 3. The reduction of p-chlorobenzenonitrile has been thoroughly studied since the resulting radical anion 17 is stabilized by the electron-withdrawing cyano group.\[20\] It is unlikely that the Grignard reagent serves as the one-electron donor at 0 °C. Since the transformation requires the presence of MnCl₂, the initiator is probably the corresponding triorganomanganese complex which is known to mediate radical reactions\[21\] and is easily formed from MnCl₂ and an organomagnesium halide.\[22\] The subsequent loss of chloride from the p-cyano radical anion is well-established and occurs with a three orders of magnitude higher rate than for the corresponding m-chlorobenzenonitrile radical anion,\[23\] which may explain the lack of reactivity of the meta substrate. The aryl radical 18 is electrophilic due to the cyano group and the ensuing nucleophilic attack can take place with either the triorganomanganese complex or with the Grignard reagent. Here, it should be noted that the transformation in Table 1, entry 1 also gives a fast reaction and a high yield with one equiv. of MnCl₂ and under these conditions there is probably no free Grignard reagent present. Accordingly, the most likely nucleophile is the triorganomanganese complex which is known to be a softer nucleophile than a Grignard reagent.\[24\] Rate constants for the reaction between aryl radicals and various nucleophiles have previously been determined and they are in most cases close to the diffusion limit.\[24\] No homocoupling of the aryl halide was ever observed in any of the experiments which again points to a very rapid conversion of the intermediate aryl radical. Finally, the cycle is closed by SET from the radical ion 19 to the starting p-chlorobenzenonitrile. The pathway may explain the limited substrate scope of the transformation since electron-withdrawing cyano/ester groups in the ortho or para positions are stabilizing radical anions 17 and 19 and at the same time facilitating the dechlorination to form the aryl radical.

The reaction was monitored by TLC and additional allyl bromide (0.6 mmol, 7.1 mmol) and K₂CO₃ (1 g, 7.2 mmol) were added after 20 min. After two hours, the reaction was diluted with water and extracted with diethyl ether. The organic layers were concentrated to give 1.2 g (95%) of a brown solid. H NMR (400 MHz, CDCl₃): δ = 7.47 (d, J = 8.1 Hz, 1H), 7.20 (d, J = 8.1 Hz, 1H), 7.12 (d, J = 8.1 Hz, 1H), 7.11 (d, J = 8.1 Hz, 1H), 7.08 (d, J = 8.1 Hz, 1H), 7.00 (d, J = 8.1 Hz, 1H), 7.00 (d, J = 8.1 Hz, 1H), 6.98 (d, J = 8.1 Hz, 1H), 6.97 (d, J = 8.1 Hz, 1H), 6.97 (d, J = 8.1 Hz, 1H), 7.17 (d, J = 7.9 Hz, 1H), 7.12 (d, J = 7.6 Hz, 1H), 2.98 (tt, J = 11.3, 3.1 Hz, 1H), 2.53 (s, 3H), 1.95–1.72 (m, 5H), 1.57–1.35 (m, 4H), 1.34–1.17 (m, 1H) ppm. 13C NMR (100 MHz, CDCl₃): δ = 151.9, 142.3, 132.4, 127.5, 127.3, 117.3, 112.5, 43.1, 33.9, 26.8, 26.1, 21.1 ppm. MS (EI): m/z = 199 [M⁺].
3-Methyl-2,3-dihydrobenzofuran-6-carbonitrile (15): Ally ether 13 (386 mg, 2 mmol) was reacted with cyclohexylmagnesium chloride and MnCl₂ as described above in the general procedure to give 31.1 mg (9%) of the product as a brown oily solid. ¹H NMR (400 MHz, CDCl₃): δ = 7.21 (d, J = 7.7 Hz, 1H), 7.17 (dd, J = 7.7, 1.3 Hz, 1H), 6.99 (d, J = 1.2 Hz, 1H), 4.74 (t, J = 9.0 Hz, 1H), 4.14 (dd, J = 8.8, 7.4 Hz, 1H), 3.65–3.50 (m, 1H), 1.34 (d, J = 6.9 Hz, 3H) ppm. ¹³C NMR (100 MHz, CDCl₃): δ = 160.0, 138.5, 125.3, 124.7, 119.2, 112.7, 111.6, 79.1, 36.1, 19.1 ppm. HRMS: calcd for C₁₁H₁₁N₂Na₂O₂ [M + Na]⁺: 218.0577, found: 218.0577.

1-Methyl-2,3-dihydro-1H-indene-5-carbonitrile (16): Butenyl compound 14 (382 mg, 2 mmol, including 30% of the olefin isomer) was reacted with cyclohexylmagnesium chloride and MnCl₂ as described above in the general procedure to give 21.7 mg (7%) of the product as a colorless solid. ¹H NMR (400 MHz, CDCl₃): δ = 7.47 (s, 1H), 7.46 (d, J = 7.5 Hz, 1H), 7.25 (d, J = 7.1 Hz, 1H), 3.27–3.17 (m, 1H), 2.94 (ddd, J = 16.2, 8.7, 4.0 Hz, 1H), 2.86 (dt, J = 16.4, 8.5 Hz, 1H), 2.35 (dt, J = 11.4, 7.4, 3.7 Hz, 1H), 1.65 (dq, J = 12.6, 8.7 Hz, 1H), 1.30 (d, J = 6.9 Hz, 3H) ppm. ¹³C NMR (100 MHz, CDCl₃): δ = 154.6, 145.2, 130.7, 128.3, 124.1, 119.8, 103.9, 39.9, 34.5, 31.3, 19.5 ppm. HRMS: calcd for C₁₅H₁₂NNa₂O₂ [M + H]⁺: 258.0964, found: 258.0964.

**FULL PAPER**

**Formed by radicals:** Aryl halides and Grignard reagents are coupled with MnCl₂ as catalyst. The substrate scope and the mechanism are investigated, and an aryl radical is identified as an intermediate. As a result, the cross coupling is believed to proceed through a S_{N}1 mechanism.
