**ABSTRACT:** Benefiting from the specially tailored properties of the building blocks as well as of the scaffolds, DNA-assembled core-satellite superstructures have gained increasing interest in drug delivery, imaging and biosensing. The load of satellites plays a vital role in core-satellite superstructures and it determines the signal intensity in response to a biological/physical stimulation/actuation. Herein, for the first time, we utilize on-particle rolling circle amplification (RCA) to prepare rapidly responsive core-satellite magnetic superstructures with a high load of magnetic nanoparticle (MNP) satellites. Combined with duplex-specific nuclease assisted target recycling, the proposed magnetic superstructures hold great promise in sensitive and rapid microRNA detection. The long single-stranded DNA produced by RCA serving as the scaffold

1  
2  
3 of the core-satellite superstructure, can be hydrolyzed by duplex-specific nuclease in the  
4 presence of target microRNA, resulting in a release of MNPs that can be quantified in an  
5 optomagnetic sensor. The proposed biosensor has a simple mix-separate-measure strategy. For  
6 let-7b detection, the proposed biosensor offers a wide linear detection range of approximately  
7 five orders of magnitude with a detection sensitivity of 1 fM. Moreover, it has the capability to  
8 discriminate single-nucleotide mismatches and to detect let-7b in cell extracts and serum, thus  
9 showing considerable potential for clinical applications.

## INTRODUCTION

Point-of-care diagnostics is one of the principal motivations behind the current development of nanotechnology. The various requirements for point-of-care diagnostics, *e.g.*, ease-of-use, short assay time, high sensitivity and low cost, are challenging for traditional analytical methods and in most cases beyond the capability of monofunctional-material-based biosensors.<sup>1-3</sup> In order to strengthen the performance of biosensors, materials with different functionalities are commonly used simultaneously. In contrast to the utilization of a mixture of different materials, using the assembly of various simple building blocks offers further improvement of the biosensing performance, and has a much broader range of applications since it takes advantage of both the intrinsic and collective properties of the constituents.<sup>4-7</sup> Owing to the predictability, specificity, and diversity of hybridization, DNA as a scaffold/spacer shows great potential in assembling nano- to micron-sized superstructures.<sup>8-11</sup> In particular, the use of DNA-assembled core-satellite superstructures in biosensing applications enables control of the dimension, composition, functionality of the core/satellite building blocks and of the sequence of DNA scaffold/spacer. It is thereby a flexible tool to meet the requirements for clinical diagnostics.<sup>12-18</sup>

In our previous work, a multilayer core-satellite magnetic superstructure was reported for RNA biosensing.<sup>19</sup> As a consequence of the duplex-specific nuclease (DSN) assisted DNA hydrolysis, satellites were released from the core-satellite magnetic superstructures into the suspension and measured. The as-reported multilayer core-satellite magnetic superstructure offered advantages of: (a) easy manipulation because of the magnetic micron-sized core, (b) multiplexing because of the controllable release of different nano-sized satellites, and (c) predictable enzyme-based reactions because of the programmable DNA scaffold/spacer. However, the layer-by-layer material preparation, *i.e.*, conjugating one end of the DNA probes to the surface of the core

1  
2  
3 followed by conjugating satellites to the other end of the DNA probes, limited the load of  
4 satellites and thus affected the sensitivity of the biosensor. Additionally, in this preparation  
5 method, satellites were often linked to the core *via* more than one DNA probe, which further  
6 reduced the sensitivity of the biosensor since several DNA hydrolysis reactions were required to  
7 release a single satellite.<sup>13,19</sup>

15  
16

17 In order to address the issues faced by layer-by-layer preparation based core-satellite  
18 superstructures, we herein take advantage of an on-particle rolling circle amplification (RCA)  
19 based method for improved preparation of core-satellite magnetic superstructures. RCA is a  
20 simple and efficient isothermal amplification tool that produces long single-stranded DNA  
21 (ssDNA) molecules with programmable repeating sequences, which can further be utilized as  
22 scaffolds for assembling nanostructures into one-dimensional superstructures.<sup>20-23</sup> Moreover, the  
23 RCA reaction can be performed on the surface of a particle (on-particle RCA) followed by  
24 assembling nano-sized satellites, which provides programmable three-dimensional core-satellite  
25 superstructures.<sup>24-28</sup> Here, we develop on-particle RCA with biotinylated DNA building blocks to  
26 prepare core-satellite magnetic superstructures with a high load of magnetic nanoparticle (MNP)  
27 satellites. The on-particle RCA products contain repeating sequences that can hybridize to target  
28 RNAs, forming DNA:RNA heteroduplex structures, which can subsequently be cleaved by DSN.  
29 The RNA strands are preserved in the hydrolysis and then released to the suspension to trigger  
30 more reactions. This process, denoted DSN-assisted target recycling,<sup>29-34</sup> cleaves on-particle  
31 RCA based core-satellite superstructures and releases one-dimensional assemblies of MNPs. The  
32 one-dimensional superstructures can be further cleaved as the DSN-assisted target recycling  
33 continues to release individual MNPs.

MicroRNAs are 19 to 23-nucleotide long tissue-specific biomarkers for tumor progression and metastasis.<sup>35-38</sup> Standard RNA analysis strategies, *i.e.*, Northern blotting,<sup>39,40</sup> oligonucleotide microarrays,<sup>41,42</sup> and quantitative reverse transcription polymerase chain reaction (qRT-PCR),<sup>43,44</sup> have been widely used for microRNA analysis, but still have their own limitations, *e.g.*, low sensitivity, labor-intensive processes, or lack of 5'-end specificity.<sup>45,46</sup> By the combination of on-particle RCA based core-satellite magnetic superstructures, DSN-assisted target recycling and the 405 nm laser-based optomagnetic sensor, we demonstrate a homogeneous and volumetric detection biosensor for microRNA. Relying on the high load of MNPs, the on-particle RCA based method shows improvements in terms of response speed, signal amplitude and sensitivity in comparison with our previous work which used layer-by-layer assembled core-satellite magnetic superstructures. As far as we know, this is the first demonstration of a biosensor based on the combination of RCA and DSN-assisted target recycling.

## RESULTS AND DISCUSSION

**Detection Principle.** On-particle RCA produces long ssDNA containing repeating DNA sequences that are complementary to the target RNA, *i.e.*, let-7b used in this study. The ssDNA is serving as a scaffold to assemble MNPs onto micro-particle (MP) cores to form on-particle RCA based core-satellite superstructures (MP-RCA-NPs). Target RNA molecules present in the suspension can hybridize to the ssDNA scaffolds to form DNA:RNA heteroduplexes, which can be recognized and cleaved by DSN, resulting in a release of MNPs from the MP-RCA-NP superstructures. The target RNA is preserved in the DSN-based hydrolysis and is thus able to

bind to other complementary sequences on the same or on another ssDNA scaffold. The working principle is schematically illustrated in **Figure 1**.

**Figure 1.** Working principle of microRNA detection based on MP-RCA-NP superstructures and DSN-assisted target recycling. Target RNA hybridizes to an ssDNA scaffold and forms a DNA:RNA heteroduplex. The DNA:RNA heteroduplex is cleaved by DSN and MNPs are subsequently released. The target RNA is preserved in the reaction and is thus able to bind to other complementary sequences on the same or on another ssDNA scaffold.

MNPs released to the suspension are quantified with a 405 nm laser-based optomagnetic sensor. The sensor records the second harmonic modulation of the transmitted light intensity in response to an applied field  $B(t)=B_0\sin(2\pi ft)$ . The output signal,  $V_2'/V_0$ , is the real ( $\sin(4\pi ft)$ ) part of the second harmonic component of the transmitted light intensity normalized by the simultaneously measured total transmitted light intensity. A typical  $V_2'/V_0$  spectrum in this study is characterized by a peak located around 200 Hz representing the response from suspended MNPs,

1  
2  
3 which is used for the quantification of target microRNA. Detailed description as well as the  
4 underlying theory of the 405 nm laser-based optomagnetic sensor can be found in our previous  
5 publications.<sup>47-51</sup>

10  
11  
12 **Characterization of On-Particle RCA Based Core-Satellite Magnetic Superstructures.** To  
13 prepare MP-RCA-NP superstructures, biotinylated dUTPs are used to replace a part of dTTTPs as  
14 DNA building blocks during the on-particle RCA. The utilization of biotin-dUTP results in  
15 ssDNA products containing biotin groups that can subsequently assemble streptavidin coated  
16 MNPs. To study the performance of the MP-RCA-NP superstructures and to compare with  
17 ssDNA probe based MP-NP superstructures, on-particle RCA reactions were performed with  
18 high or low biotin-dUTP concentrations, by employing biotin-dUTP:dTTTP ratios of 3:1 or 1:3,  
19 respectively. In **Figure 2a** and **b** scanning electron microscopy (SEM) micrographs are shown  
20 for MP-RCA-NP superstructures with high or low MNP loads, respectively. From the SEM  
21 micrographs it can be concluded that the MNPs are assembled on the MP cores. Due to the  
22 assembly of several MNPs on the same ssDNA molecule forming a random-coil structure, drying  
23 effect, and the nonspecific binding between nearby ssDNA strands, MNPs are not uniformly  
24 distributed but form islands on the MP-RCA-NP superstructures. The size of MNP islands is  
25 influenced by the concentration of biotin-dUTP used in RCA, *i.e.*, a higher biotin-dUTP:dTTTP  
26 ratio leads to a higher MNP load of the superstructure and thus larger MNP islands on MPs. As a  
27 comparison, **Figure 2c** shows the morphology and structure of the ssDNA probe based MP-NP  
28 superstructures, on which the MNPs are uniformly distributed.

1  
2  
3 The sensitivity and accuracy of core-satellite superstructure based biosensors are strongly  
4 influenced by the load of releasable MNP satellites. To evaluate the capability of releasing  
5 MNPs, three different kinds of core-satellite superstructures (MP-RCA-NPs with high MNP  
6 load, MP-RCA-NPs with low MNP load and MP-NPs) were reacted with 10 nM of let-7b to  
7 cleave ssDNA through DSN-assisted target recycling. For the MP-RCA-NPs with high and low  
8 MNP loads, the signal increased at a higher rate than for the MP-NPs during the first 30 min of  
9 the reaction. This implies that fewer DSN-based hydrolysis reactions were needed for MP-RCA-  
10 NPs to release MNPs (cf. slopes of lines in **Figure 2d**). Due to the layer-by-layer preparation of  
11 the MP-NP superstructures, MNPs were linked to the MP core *via* more than one ssDNA probe,  
12 resulting in a slower response to targets.<sup>19</sup> From analysis of the concentration of MNPs released  
13 from the superstructures after an incubation time of 90 min, the average ratios between MP cores  
14 and MNP satellites were calculated to 1:143, 1:75 and 1:73 for MP-RCA-NPs with high MNP  
15 load, MP-RCA-NPs with low MNP load and MP-NPs, respectively (Supporting Information,  
16 **section S1**). Although the MP-RCA-NPs with low MNP load and MP-NPs have similar  
17 MP:MNP ratio, their arrangement and distribution of MNP satellites are very different.

35  
36  
37  
38  
39  
40 The arrangement of MNPs on the RCA products is another critical parameter that influences the  
41 analytical performance of the MP-RCA-NP superstructures. Biotin groups are randomly  
42 distributed along the ssDNA. A high MNP load means a high-density arrangement of MNPs on  
43 the ssDNA (illustration in **Figure 2a**). Moreover, since there are more target-recognizing  
44 sequences between two nearby MNPs on the same ssDNA for a low-density MNP arrangement  
45 (illustration in **Figure 2b**), fewer MNPs are released by each DSN-based hydrolysis reaction,  
46 resulting in a lower rate of the signal increase, see **Figure 2d** where blue circles and red

1  
2  
3 diamonds represent high-density and low-density MNP arrangements, respectively. However,  
4 since the target recognizing sequences in the ssDNA also contain biotin groups that can bind to  
5 the MNPs, a high-density MNP arrangement may hinder the hybridization of target microRNA  
6 as well as the DSN-based hydrolysis, which leads to an increased number of un-releasable  
7 MNPs. Despite this small drawback, we still chose MP-RCA-NP with a high-density MNP  
8 arrangement for the following experiments to obtain a better accuracy with a quicker response.

3 satellite superstructures reacted with 10 nM of let-7b. All the measurements were performed  
4  
5 three times independently and the standard deviations were plotted as error bars.  
6  
7  
8  
9

10 **Quantitative MicroRNA Detection.** The quantification of target microRNA using the high  
11 MNP load MP-RCA-NPs was investigated. The target RNA, let-7b, was diluted by the reaction  
12 buffer to a series of concentrations ranging from 1  $\mu$ M to 10 aM, followed by reaction with MP-  
13 RCA-NPs and DSN cleaving for 60 min. Thereafter, the concentration of MNPs in the  
14 suspension, mainly released from the core-satellite superstructures (see Supporting Information,  
15 **section S1**), was measured by the optomagnetic sensor. As shown in **Figure 3a**, the peak in the  
16  $V_2'/V_0$  spectra, representing the signal from suspended 100 nm MNPs, increased monotonously  
17 with increasing let-7b concentration. Although centrifugation was adopted as the last step in the  
18 preparation protocol for the superstructures to remove unbound MNPs, it could not provide  
19 conditions for complete removals, thereby resulting in a background signal for all of the  
20 measurements. When measuring low target concentrations, the peak positions were slightly  
21 shifted to the low-frequency region, implying the presence of suspended dimers and/or short  
22 chains of MNPs. **Figure 3b** shows the  $V_2'/V_0$  peak amplitudes plotted against the target  
23 concentration. From the dose-response curve it can be seen that the linear detection range spans  
24 over approximately five orders of magnitude (10 fM to 1 nM) and that there exists a signal  
25 plateau at high target concentrations ( $\geq 10$  nM). The red dashed line in **Figure 3b** indicates the  
26 cutoff value, which was calculated based on the three-sigma criterion, *i.e.*, the average peak  
27 value of the blank controls plus three times of their standard deviations. The limit of detection  
28 (LOD) of the proposed biosensor, defined as the lowest target concentration that can generate a  
29 peak amplitude higher than the cutoff value, was obtained as 1 fM. The average coefficient of

2  
3 variation (CV) was 4.1%, indicating high reproducibility. The major factors which cause  
4 variations in measured peak amplitudes are most likely sample-to-sample variations in the  
5 concentration of superstructures and temperature fluctuations during the DSN-assisted release of  
6 MNP satellites. For plasma, the total microRNA concentration was reported to be at the 100 fM  
7 level,<sup>52</sup> implying that the femtomolar level LOD provided by the proposed biosensor is sufficient  
8 for microRNA analysis in plasma. It should be emphasized that the LOD and detection range can  
9 be further adjusted by simply choosing different reaction times for DSN-assisted target  
10 recycling.

11  
12  
13  
14  
15  
16  
17 Compared to the MP-NP superstructure based microRNA detection in our previous work,<sup>19</sup> the  
18 MP-RCA-NP based biosensing shows improvements in both signal amplitude and reaction  
19 speed. Relying on the high load of MNP satellites, MP-RCA-NP superstructures can release  
20 more MNPs than MP-NP superstructures, thereby offering almost doubled optomagnetic peak  
21 amplitudes without increasing CVs and thus improved accuracy. In addition, since fewer DSN-  
22 based hydrolysis reactions are needed for MP-RCA-NPs than for MP-NPs to release a certain  
23 number of MNPs, MP-RCA-NPs show a faster response to target molecules present in low  
24 concentrations. However, MP-RCA-NPs release chains of MNPs instead of individual ones  
25 when reacted with target molecules of low concentrations; these chains have very low  
26 optomagnetic signals and nearly negligible contributions to the peak amplitude located around  
27 200 Hz, which influences the sensitivity of the proposed biosensor. As a result, the MP-RCA-NP  
28 based biosensor is approximately 5 times more sensitive than the previous method based on MP-  
29 NP superstructures.

3 (electrochemical impedance spectroscopy),<sup>53</sup> 0.1 fM (UV-vis spectroscopy),<sup>54</sup> 0.3 fM (surface-  
4 enhanced Raman spectroscopy),<sup>55</sup> 0.5 fM (UV-vis spectroscopy),<sup>56</sup> 3.36 fM (magnetic relaxation  
5 switch sensor),<sup>31</sup> 1 pM (UV-vis spectroscopy),<sup>34</sup> 1.03 pM (fluorescence spectroscopy)<sup>33</sup> and 1.1  
6 pM (fluorescence spectroscopy)<sup>57</sup> were reported for the detection of different microRNAs.  
7  
8 However, except for the magnetic relaxation switch biosensor, all these biosensors need  
9 additional pretreatment, washing or signal generation steps, which limit their potential for point-  
10 of-care applications. In comparison, the proposed MP-RCA-NP superstructure based  
11 optomagnetic biosensor has a simple mix-separate-measure strategy which can be easily  
12 integrated into microfluidic systems.<sup>58</sup>

26 **Specificity Test.** Due to the strong sequence homology between different microRNAs within the  
27 same family discrimination between these is complicated. The specificity of the proposed  
28 method for let-7b against other control microRNAs was tested by comparing the optomagnetic  
29 peak amplitudes obtained from 0.1 nM of different let-7 microRNAs (using MP-RCA-NPs with  
30 a high MNP load, **Figure 4**). Sequences of the let-7 microRNAs measured in this study and the  
31 differences among them are summarized in **Table S2**. The two highest nonspecific signals,  
32 obtained from 0.1 nM of let-7c (single-nucleotide mismatches) and 0.1 nM of let-7a (double-  
33 nucleotide mismatches), were found to be equal to the signals of 1.7 and 0.3 pM of let-7b,  
34 respectively. Nonspecific signals were induced by the 16-bp-long perfect DNA:RNA  
35 heteroduplexes formed between the non-target microRNAs (let-7c and let-7a) and the  
36 recognition sequences on the RCA products. From the results of the specificity test it is evident  
37 that the proposed method is capable of discriminating between sequences containing even single-  
38 nucleotide mismatches.

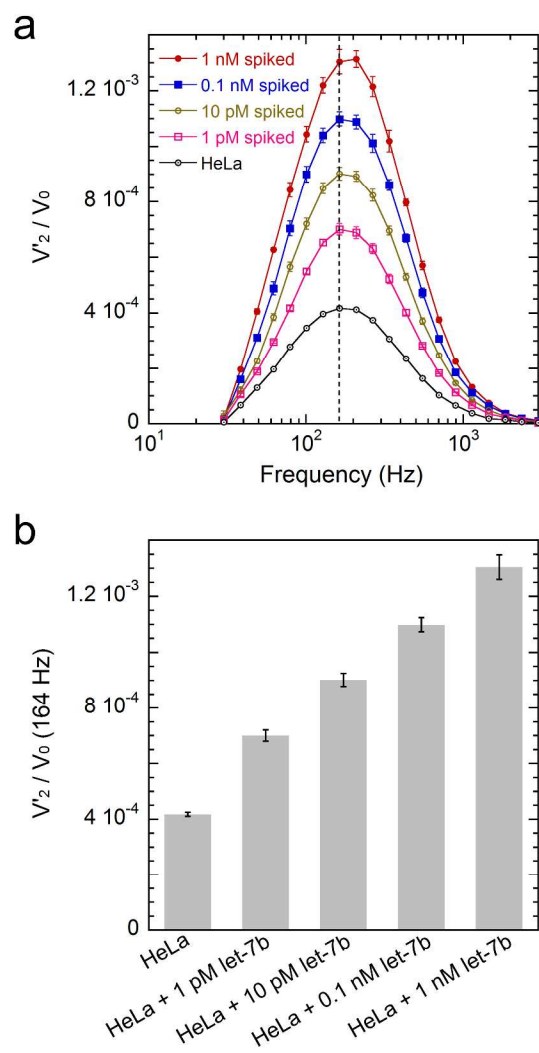

**Figure 4.** Specificity test for the proposed let-7b detection method using high MNP load MP-RCA-NPs. Optomagnetic peak amplitudes for five different types of let-7 microRNA (0.1 nM) are shown. All the measurements were performed three times independently and the standard deviations were plotted as error bars.

**Detection of Endogenous MicroRNA from HeLa Cells.** Total RNAs that were extracted from human cervical cancer cells (HeLa) were investigated to demonstrate the performance of the MP-RCA-NP superstructure for target quantification in cell extracts. Cell extracts (containing total RNAs) were diluted by the reaction buffer to an RNA concentration of  $1 \mu\text{g mL}^{-1}$  to serve as the pure extracts. Spiked samples containing 1, 10, 100 and 1000 pM of synthetic let-7b were prepared by spiking the target RNA into pure extracts. The optomagnetic spectra and signals of the pure and spiked RNA extracts are shown in **Figure 5**. For the spectra of RNA extracts (**Figure 5a**), no shape change was observed (compare with **Figure 3a**). The let-7b concentration of the pure extracts was found to be  $39.7 \pm 3.3 \text{ fM}$  (corresponding to  $2.387 \pm 0.196 \times 10^7$  copies  $\mu\text{g}^{-1}$  total RNA) by calculating the linear fitting of the peak amplitudes obtained from the four spiked RNA extracts, which agrees well with the result obtained by qRT-PCR ( $44.3 \pm 3.7 \text{ fM}$ ).

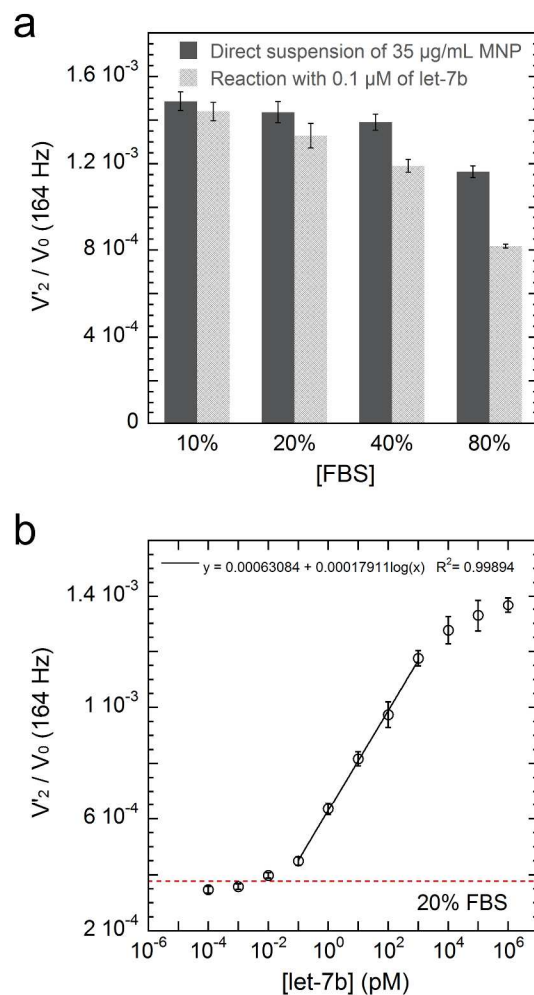

The results suggest that the MP-RCA-NP based biosensor is suitable for clinical diagnosis and prognosis applications.

**Figure 5.** Optomagnetic spectra (a) and peak amplitude (b) obtained from diluted total RNA extracts (containing  $1 \mu\text{g mL}^{-1}$  total RNA) spiked with let-7b. The black dashed vertical line in (a) indicates the peak position at 164 Hz. All the measurements were performed three times independently and the standard deviations were plotted as error bars.

1  
2  
3 **Matrix Effects and Serum Detection.** Apart from tissues, microRNAs are also circulating in  
4 body fluids such as plasma.<sup>52,59</sup> Since cell extracts have limited matrix effects, the robustness of  
5 the biosensor was further studied by using fetal bovine serum (FBS, diluted with reaction buffer,  
6 **Figure 6**). Except for increasing the viscosity of the suspension, the matrix effects of FBS  
7 mainly include: (1) inducing MNP aggregation, and (2) inhibiting the DSN-based reaction. To  
8 evaluate the aggregation effect, MNPs ( $35 \mu\text{g mL}^{-1}$ ) in different FBS solutions were measured.  
9 No significant MNP aggregation was found at FBS concentrations lower than 40% (cf. **Figure**  
10 **6a** and **S2a**). However, when the MP-RCA-NP (high MNP load) based biosensor was utilized to  
11 detect 0.1  $\mu\text{M}$  of let-7b in FBS solutions (**Figure 6a** and **S2b**), the optomagnetic signals were  
12 much lower compared to the direct suspension of MNPs, implying the inhibition caused by FBS  
13 (RNA binding proteins, nonspecific oligonucleotides, RNase, *etc.*).

30  
31 We further performed let-7b quantification in FBS using the MP-RCA-NP superstructures (high  
32 MNP load). The target RNA was spiked into 20% FBS to a series of concentrations and  
33 measured. Compared to the measurements performed in buffer solutions (**Figure 3b**), the dose-  
34 response curve shown in **Figure 6b** has a narrower linear detection range from 0.1 pM to 1 nM.  
35 Moreover, matrix effects influenced the biosensing performance and resulted in a weakened  
36 LOD of 10 fM. Considering that the real serum samples in clinical diagnostics are much more  
37 complex than FBS, RNA extraction is recommended before microRNA analysis. Spectra of the  
38 optomagnetic measurements are shown in **Figure S2c**.

All the measurements were performed three times independently and the standard deviations were plotted as error bars.

## CONCLUSIONS

In this study, on-particle RCA based core-satellite magnetic superstructures were prepared and combined with DSN-assisted target recycling for optomagnetic detection of microRNA. As far as we know, this is the first demonstration of a biosensor based on the combination of RCA and DSN-assisted target recycling. Compared to the MP-NP superstructures reported by us in earlier work,<sup>19</sup> the as-prepared MP-RCA-NPs have a doubled load of MNP satellites and need fewer hydrolysis reactions to release MNPs, thus providing improved sensing accuracy as well as sensitivity. The proposed biosensor offers a wide linear detection range (10 fM to 1 nM) with a detection sensitivity of 1 fM for let-7b detection. We have also demonstrated the ability of the proposed method to discriminate single-nucleotide mismatches and to detect let-7b in cell extracts and serum. Despite the advantages mentioned above, the MP-RCA-NP superstructure based method has some limitations for biosensing applications: (1) micro-particles easily aggregate and precipitate during the on-particle RCA process, thereby limiting the length of the RCA products; (2) a separation step is needed to remove the micro-particles after the DSN-based reaction since the micro-particles influence the optomagnetic measurement. To further improve the detection strategy to achieve a mix-measure format, MNP chains could be considered in a follow-up study. In this study RCA products serve as scaffolds to stabilize MNP chains formed in a rotating magnetic field,<sup>60</sup> thereby preparing one-dimensional superstructures that can be used for microRNA detection. In summary, by utilizing the special properties of MP-RCA-NP superstructures, DSN-assisted target recycling and optomagnetic sensing, we have presented a sensitive, rapid, homogeneous and isothermal microRNA detection method in a simple mix-separate-measure format that can be added to the toolbox for versatile clinical applications, *e.g.*,

## 10 MATERIALS AND METHODS

11  
12 **DNA and RNA Sequences.** DNA sequences including biotinylated template and padlock probe  
13 were used for on-particle RCA. Single-stranded DNA probes were used for assembling MP-NP  
14 superstructures. RNA sequences including let-7b, let-7c, let-7d and let-7e were used as the target  
15 or controls. DNA and RNA sequences are listed in **Table S2**. All sequences were synthesized by  
16 Biomers (Ulm, Germany) and dissolved in 50 mM Tris-HCl (pH 8.0) for storage at -20°C.

26 **Chemicals.** RNase inhibitor (20 U  $\mu\text{L}^{-1}$ ), Tris-HCl (1 M, pH 8.0),  $\phi 29$  polymerase,  $\phi 29$  buffer,  
27 ATP, T4 ligase, dA/T/C/GTP, biotin-11-dUTP and bovine serum albumin were purchased from  
28 Thermo Fisher Scientific (Waltham, USA). Duplex-specific nuclease was purchased from  
29 Evrogen (Moscow, Russia), dissolved in Tris-HCl (50 mM, pH 8.0) and glycerol (at 1:1 ratio)  
30 for storage at -20°C. DTT, glycerol, biotin,  $\text{MgCl}_2$  and FBS were purchased from Sigma-Aldrich  
31 (St. Louis, USA). Phosphate buffered saline (PBS, 20 $\times$ ) was purchased from AMRESCO (Solon,  
32 USA). For DSN-based reaction, the reaction buffer consisted of Tris-HCl (50 mM, pH 8.0), 20  
33 mM  $\text{MgCl}_2$  and 1 mM DTT. Streptavidin coated 100 nm MNPs (multicore magnetic beads  
34 containing clusters of small single domain particles,  $6 \times 10^{12}$  particles  $\text{mL}^{-1}$ , 10 mg  $\text{mL}^{-1}$ , product  
35 code 10-19-102) and streptavidin coated magnetic microparticles ( $5.5 \times 10^9$  particles  $\text{mL}^{-1}$ , 25 mg  
36  $\text{mL}^{-1}$ , product code 08-19-203) were purchased from Micromod Partikeltechnologie GmbH  
37 (Rostock, Germany). All the pipette tips and storage tubes were RNase-free.

MPs (2.5 mg, 100  $\mu\text{L}$  of the stock solution) were washed twice and resuspended in 200  $\mu\text{L}$  PBS  
(1 $\times$ ) before conjugation. Biotinylated RCA template (10  $\mu\text{L}$ , 1  $\mu\text{M}$ ) was pipetted into the MP  
suspension for conjugation (20 $^{\circ}\text{C}$ , 20 min). Thereafter biotin (100  $\mu\text{L}$ , 1 mM) was added to the  
suspension for blocking, and the suspension was incubated at 20 $^{\circ}\text{C}$  for 10 min. The blocked  
template-MPs were washed three times by a magnetic stand to remove unused template and  
biotin, and finally resuspended in 400  $\mu\text{L}$   $\text{H}_2\text{O}$ .

### **Synthesis of MP-RCA-NP Core-Satellite Magnetic Superstructures by On-Particle RCA.**

The ligation mixture (500  $\mu\text{L}$ ) for on-particle RCA was prepared by mixing 50  $\mu\text{L}$  of 10 $\times$  $\phi$ 29  
buffer, 25  $\mu\text{L}$  of ATP (20 mM), 10  $\mu\text{L}$  of padlock probe (1  $\mu\text{M}$ ), 10  $\mu\text{L}$  of T4 ligase (1 U  $\mu\text{L}^{-1}$ ),  
400  $\mu\text{L}$  of as-prepared template-MPs and 10  $\mu\text{L}$  of  $\text{H}_2\text{O}$ , followed by incubation at 37 $^{\circ}\text{C}$  for 15  
min. For on-particle RCA reaction (to prepare MP-RCA-NP superstructures with high MNP  
load), 500  $\mu\text{L}$  of ligation mixture (containing 2.5 mg of MPs) was mixed with 30  $\mu\text{L}$  of 10 $\times$  $\phi$ 29  
buffer, 75  $\mu\text{L}$  of dNTPs (containing 0.25 mM of dTTP, 1 mM each of dATP, dCTP and dGTP),  
75  $\mu\text{L}$  of biotin-11-dUTP (0.75 mM), 75  $\mu\text{L}$  of BSA (2  $\mu\text{g}$   $\mu\text{L}^{-1}$ ) and 25  $\mu\text{L}$  of  $\phi$ 29 polymerase  
(10 U  $\mu\text{L}^{-1}$ ), followed by incubation at 30 $^{\circ}\text{C}$  for 60 min with gentle shaking. Aggregates of MPs  
formed during the RCA reaction by coiling and nonspecific binding of ssDNA. The aggregates  
can be unfolded by incubating the suspension at 65 $^{\circ}\text{C}$  for 10 min. Thereafter the on-particle  
RCA products were washed three times with 50 mM Tris-HCl (65 $^{\circ}\text{C}$ ) using a magnetic  
separation stand, followed by adding 100  $\mu\text{L}$  of streptavidin coated 100 nm MNPs (10 mg  $\text{mL}^{-1}$ )  
and incubating at 60 $^{\circ}\text{C}$  for 15 min to form MP-RCA-NP superstructures. Unbound MNPs were  
removed by five times of centrifugation using a VWR Galaxy MiniStar microcentrifuge (2000 g,

1  
2  
3 10 s). Lastly, the MP-RCA-NP superstructures were resuspended in Tris-HCl (200  $\mu$ L, 50 mM)  
4  
5 for storage at 4°C. For the preparation of MP-RCA-NP superstructures with low MNP load, the  
6  
7 synthesis procedure was similar except for reducing the ratio of biotin-dUTP:dTTP from 3:1 to  
8  
9 1:3.  
10  
11  
12  
13

#### 14 **Synthesis of MP-NP Core-Satellite Magnetic Superstructures by ssDNA Probes.**

15  
16 Streptavidin coated MPs (2.5 mg, 100  $\mu$ L of the stock solution) were washed twice and  
17  
18 resuspended in Tris-HCl (50 mM, pH 8.0). Biotinylated ssDNA probes (120  $\mu$ L, 100  $\mu$ M) were  
19  
20 added into the MP suspension for conjugation (20°C, 20 min). After that, the ssDNA probe-MPs  
21  
22 were washed three times by a magnetic stand to remove unused probes, and resuspended in Tris-  
23  
24 HCl (100  $\mu$ L, 50 mM). Streptavidin coated 100 nm MNPs (100  $\mu$ L, 10 mg mL<sup>-1</sup>) were mixed  
25  
26 with the ssDNA probe-MPs, followed by incubation at 20°C for 15 min. MNPs that have not  
27  
28 bound to the MP were removed by five times of centrifugation. Lastly, the superstructures were  
29  
30 resuspended in Tris-HCl (200  $\mu$ L, 50 mM) for storage at 4°C.  
31  
32  
33  
34  
35  
36  
37

38 **MicroRNA Detection Using DSN-Assisted Target Recycling.** For let-7b detection, 91.5  $\mu$ L of  
39  
40 the sample (containing target microRNA), 2.5  $\mu$ L of RNase inhibitor (20 U  $\mu$ L<sup>-1</sup>), 1  $\mu$ L of DSN  
41  
42 (1 U  $\mu$ L<sup>-1</sup>) and 5  $\mu$ L of core-satellite magnetic superstructures were mixed and incubated at 60°C  
43  
44 for 1 h. After the reaction, separation was performed either by centrifugation (2000 g, 10 s) or  
45  
46 standing (10 min) to separate the released MNPs from the MPs. Herein we chose centrifugation  
47  
48 for the separation step. The suspension containing released MNPs was pipetted to a UV-  
49  
50 transparent cuvette (REF 67.758.001, Nümbrecht, Germany) for optomagnetic measurement.  
51  
52  
53  
54 Three independent measurements were performed for each sample.
