Abstract

Application of QuEChERS as a new quick and easy method for screening of polycyclic aromatic hydrocarbons (PAHs) was developed, validated and used for quantification (GC-QTOF-MS) of 4 PAHs, namely benz[*a*]anthracene, chrysene, benzo[*b*]fluoranthene and benzo[*a*]pyrene. A clean-up step using Zirconium based dispersive SPE was applied. Validation based on spiked samples (0.5, 1 and 4 µg/kg) revealed a limit of quantification (LOQ) for the 4 PAH compounds in the range of 0.14-0.24 µg/kg for fish and 0.12-0.24 µg/kg for raw barley. Overall recoveries ranged from 88 to 117% with repeatability and in-house reproducibility from 2.6 to 16%. The method was applied to 9 malt samples which were found to contain the sum of 4 PAH from <0.36 µg/kg for raw barley to 26 µg/kg for peat smoked barley. For 5 smoked fish samples the sum of PAH4 ranged from <0.34 µg/kg for cold smoked salmon to 2.2 µg/kg for hot smoked mackerel. In general it was found that the method could be used as a fast screening for evaluation of smoked fish according to EU Commission maximum concentrations of benzo[*a*]pyrene (2.0 µg/kg) and the sum of PAH4 (10 µg/kg).

Keywords: GC-Q-TOF-MS, PAH4, QuEChERS, benzo[*a*]pyrene, fish, malt

30 1. Introduction

31 Polycyclic aromatic hydrocarbons (PAHs), is a group of organic compounds that contains two or
32 more aromatic rings. PAHs have a low solubility in water and are highly lipophilic (IPCS, 1998).
33 PAHs are formed by incomplete combustion of organic materials, such as fossil fuels or wood,
34 waste incineration and tobacco smoke. Human exposure to PAHs occurs as a result of exposure to
35 environmental sources as well as food intake, where the PAHs are formed during processing of the
36 food, such as drying, smoking or barbecuing.

37
38 Studies have shown that some PAHs are genotoxic and carcinogenic. In 2002, the Scientific
39 Committee of Food (SCF) evaluated 33 PAHs resulting in 15 of these showing evidence of
40 genotoxicity and 14 of the 15 showing carcinogenic effects in experimental animals (SCF, 2002).
41 After this, the European commission established maximum limits for benzo[*a*]pyrene (BaP) for
42 certain food (EC 2005b). At the same time the European commission established a recommendation
43 on data collection of 15 PAHs in food namely benz[*a*]anthracene (BaA), benzo[*b*]fluoranthene
44 (BbF), benzo[*k*]fluoranthene (BkF), benzo[*ghi*]perylene (BghiP), benzo[*a*]pyrene, BaP, chrysene
45 (CHR), dibenz[*ah*]anthracene (DBahA), indeno[1,2,3-*cd*]pyrene (IND), benzo[*j*]fluoranthene (BjF),
46 cyclopental[*cd*]pyrene (CP), dibenzo[*ae*]pyrene (DBaeP), dibenzo[*ah*]pyrene (DBahP),
47 dibenzo[*ai*]pyrene (DBaiP), dibenzo[*al*]pyrene (DBalP) and 5-methyl chrysene (5MCHR)) (EC
48 2005a). At the same time JECFA re-evaluated the results of SCF and concluded that 13 out of the
49 15 PAHs SCF found were clearly genotoxic and carcinogenic (JECFA, 2005). They identified an
50 additional compound, benzo[*c*]fluorine (BcF). In 2008, the EFSA Panel of Contaminants in the
51 Food Chain (CONTAM Panel) reviewed data of occurrence and toxicity of the now 15+1 PAHs.
52 EFSA concluded that the sum of 8 PAHs (PAH8: BaA, BaP, BbF, BkF, BghiP, CHR, DBahA and
53 IND) and 4 PAHs (PAH4: BaA, BaP, CHR and BbF) should be used as a marker of carcinogenic
54 effects and genotoxicity of PAHs in food, where PAH8 did not provide a significant amount of
55 extra information compared to PAH4 (EFSA, 2008). Therefore, the legislation was changed to
56 include a maximum level of BaP and the sum of PAH4 (EC 2006 with amendments).

57 PAH analysis of food generally consists of three steps, an extraction of PAH and fat, followed by
58 one or more clean-up steps, and finally the detection. Analysis of PAHs in food can be tedious and
59 time consuming because of interfering compounds such as fat, and the method often depends on the
60 used matrix. An example is the analysis of PAH in olive oils with liquid-liquid extraction (LLE),
61 adsorption chromatography, thin layer chromatography (TLC) followed by detection by gas
62 chromatography (GC) with flame ionization detection (FID), GC-FID (Menichini, E. et al., 1991).
63 Sample preparation techniques for PAH analysis have also included saponification (Rose et al.,
64 2007, Akdogan et al., 2016) followed by purification by e.g. gel permeation chromatography (GPC)
65 or solid phase extraction (SPE) or both. Also coffee complex formation has been used for clean-up
66 (Welling and Kaandorp, 1986). Recent methods has included faster extraction methods such as
67 microwave assisted extraction (MAE) or pressurized liquid extraction (PLE), however still
68 combined with additional time-consuming clean-up steps such as GPC or SPE (Purcaro et al., 2009;
69 Jira, W et al., 2008; Duedahl-Olesen et al., 2010). Detection principles vary and include e.g. liquid
70 chromatography (LC) combined with fluorescence detection (FLD) (Purcaro et al. 2009; Akdogan

71 et al., 2016) and ultra violet (UV) detection (Dost and Ideli, 2012), GC combined with flame
72 ionization detection (Menichini et al., 1991; Olatunji et al. 2014) or the more recent combination of
73 both LC and GC with mass spectrometry (MS) detection (Hollosi and Wenzl, 2011; Rose et al.,
74 2007; Jira et al., 2008; Duedahl-Olesen et al., 2010). Research in faster extraction methods and the
75 producer driven need for fast screening techniques has led to the introduction of new methods. The
76 QuEChERS (Quick, Easy, Cheap, Effective, Rugged, and Safe) method has shown to provide the
77 same qualities of results as the traditional methods in food and feed analysis of e.g. pesticide
78 analysis and mycotoxins (Payá, P *et al*, 2007 and Cunha, S. *et al* 2010). Acetonitrile is often used in
79 the extraction step and an extraction salt including desiccant magnesium sulphate (MgSO_4) and
80 sodium acetate (NaOAc) or sodium chloride (NaCl) are applied. The clean-up step was simplified by
81 replacing e.g. a slow GPC separation with simply adding dispersive-SPE material to the sample.
82 Single attempts on application of QuEChERS for PAH analysis has been applied on few matrices
83 e.g. meat (Surma et al., 2014), fish (Forsberg, N.D. *et al.*, 2011) and tea (Sadowaska-Rociek, A. *et*
84 *al.*, 2013) all using GC-MS detection. The benefits of using the QuEChERS method instead of the
85 other methods, is that the method is less time-consuming and more effective, while 10 to 12
86 samples can be processed within 35-40 minutes, instead of using 24 work hours (3 work days) with
87 the traditional method. Thereby the capacity of sample preparation is increased tremendously.
88 Furthermore, the method is more environmental friendly with its minimal use of solvents and non-
89 special requirement of equipment in the clean-up step. In this study, we therefore present a
90 validated fast QuEChERS method combined with GC-Q-TOF-MS detection (accurate mass) for
91 screening analysis of 15 PAH focusing on 4 marker PAH in two distinct matrices namely malt and
92 fish with high dry matter contents and various fat contents, respectively.

93

94 **2. Material and methods**

95 **2.1. Chemicals**

96 Acetone and toluene of glass distilled grade and acetonitrile of HPLC grade S was all purchased
97 from Rathburn (Microlab, Århus, DK). n-hexane (HPLC grade) was purchased from Merck,
98 Germany. Deionised water ($18.2 \text{ M } \Omega \text{ cm}^{-1}$) produced by Mill-Q system from Millipore, (Molsheim,
99 France). An extraction salt, SupelTM QuE non-buffered (Product nr. 55294-U) and SupelTM QuE Z-
100 sep+, 500 mg (Product nr. 55296-U) both obtained from Supelco, USA. FAPAS 0668 smoked fish,
101 ISO certified reference material for quality control (truness) were obtained from FAPAS, Fera
102 Science Ltd, National Agri-Food Innovation Campus (Sand Hutton, York, UK). The certified
103 material contained BaA ($32 \pm 6.68 \text{ } \mu\text{g/kg}$), CHR ($31.4 \pm 6.90 \text{ } \mu\text{g/kg}$), BbF ($14.8 \pm 3.26 \text{ } \mu\text{g/kg}$), BaP
104 ($12.6 \pm 2.77 \text{ } \mu\text{g/kg}$), BghiP ($7.08 \pm 1.56 \text{ } \mu\text{g/kg}$) and IND ($6.63 \pm 1.46 \text{ } \mu\text{g/kg}$).

105

106 Standard solution (STD), consisting of 15 PAHs: Acenaphthene (ACN), Acenaphthylene (ACY),
107 Anthracene (ANT), BaA, BbF, BkF, BghiP, BaP, CHR, DBahA, Fluoranthene (FLA), Fluorene
108 (FLU), IND, Phenanthrene (PHE), Pyrene (PYR) each at 1000 ng/mL. Internal standard solution
109 (ISTD), 1000 ng/mL of each of 15 deuterium labelled PAHs: Acenaphthene D₁₀ (ACN D₁₀),
110 Acenaphthylene D₈ (ACY D₈), Anthracene D₁₀, (ANT D₁₀), Benz[a]anthracene D₁₂, (BaA D₁₂),

111 Benzo[*b*]fluoranthene D₁₂ (BbF D₁₂), Benzo[*k*]fluoranthene D₁₂ (BkF D₁₂), Benzo[*ghi*]perylene D₁₂
112 (BghiP D₁₂) Benzo[*a*]pyrene D₁₂ (BaP D₁₂) Chrysene D₁₂ (CHR D₁₂) Dibenz[*ah*]anthracene D₁₄
113 (DBahA D₁₄) Fluoranthene D₁₀ (FLA D₁₀) Fluorene D₁₀ (FLU D₁₀), Indeno[1,2,3-*cd*]pyrene D₁₂
114 (IND D₁₂) Phenanthrene D₁₀ (PHE D₁₀), Pyrene D₁₀ (PYR D₁₀) Both were obtained from Dr.
115 Ehrenstorfer GmbH (Augsburg, Germany) stored at -20°C.

116 **2.2. Samples and sample preparation**

117 For the validation, two types of fish, a raw cod (0.6 % fat) and a raw salmon (12 % fat) obtained
118 from the local fishmonger, Mørkhøj, DK and raw barley with 91 % dry matter were used. Smoked
119 fish from the local fish monger (Mørkhøj, Denmark) and malt samples (dry matter 91-96 %) from
120 Maltbazaren (Maltbazaren ApS est 2004) were purchased for analysis. Bones and skin were
121 removed from the fish before homogenization (Kenwood, FP220 series, Hampshire, UK). Barley
122 and malt samples were homogenized by a Coffee mill (Bosch KM13 coffee grinder). These
123 matrices with variable fat content and high dry matter content were applied to evaluate QuEChERS
124 method for PAH analysis of variable matrices.

125 **2.3. Sample preparation with QuEChERS**

126 Internal standard, ISTD (fixed concentration of 40 ng/mL) was added to 2.5 g homogenized fish or
127 5 g homogenized barley or malt in a 50 mL Centrifuge tube (Sarstedt AG&Co, Numbrecht,
128 Germany) followed by 10 mL milliQ Water, 10 mL Acetonitril, and a ceramic stone. Samples were
129 mixed 15 min. by a Genogrinder (SPEX sample prep, Ramcon, Denmark) at 750 rpm. SupelTM QuE
130 non-buffered salt was added and mixed for 5 min. at 750 rpm. The sample was then centrifuged
131 (Varifuge 3.0 R, Heraeus, Denmark) at 4000 G for 10 min. The supernatant, approximately 9 mL,
132 was extracted and frozen at -80°C. The next day, the sample was thawed and centrifuged for 5 min.
133 at 4000 G and 5°C. Then 7 mL was transferred to a new tube and the Z-sep+ dispersive SPE
134 material was added and mixed for 1 min at 750 rpm followed by centrifugation for 5 min (4000 G,
135 5°C). 5 mL supernatant was then transferred to a glass tube and evaporated to dryness with
136 nitrogen. Lastly, the sample was dissolved in toluene (200µl), shaken, filtered and transferred to a
137 GC-glass vial before analysis by GC-Q-TOF-MS. Spiked samples at 0.5, 1 and 4 µg/kg were made
138 for validation by addition of standard STD and as described above ISTD. Blind samples without
139 spike as well as reagent blanks (no sample matrix, only reagents) were included in every series to
140 make sure that no PAHs was detected in the fish and malt used for fortification and that no
141 background levels from solvents, salts or dispersive material were found.

142 Dry matter were determined by drying 0.5 g sample at 102°C for 3 hr followed by desiccating to
143 constant weight.

144 Fat content was determined by gravimetric determination of acetone:hexane (1:3) extracts from
145 pressurized liquid extraction (PLE) at 110°C (6 min heating), 2 cycles with a purge time at 60 sec
146 and 100% flush volume at 1500 psi.

147 **2.4. GC-Q-TOF-MS**

148 Analysis was performed using an Agilent GC-Q-TOF-MS (Santa Clara, USA). The GC Model was
149 7890A and the MS was 7200 Accurate-Mass Q-TOF GC/MS. Separation was achieved by two
150 coupled HP5MS ultra inert capillary columns (Agilent Technology, 15 m x 250 µm x 0.25 µm).

151 Helium was used as carrier gas at 1.2 ml/min. Programmed Temperature Vaporization (PTV)
152 injection of 3 μ L at 50 °C in solvent-vent mode , for 0.8 min. with a temperature raise to 290°C
153 held for 2 min, followed by an increase to 330°C kept for 10 min. The column separation was
154 obtained by a temperature gradient starting at 70°C for 3.3 min, increased to 180°C at the rate of
155 50°C/min, then increased to 230°C at a rate of 4°C/min, and then further increased to 280°C with 3
156 °C/min, and finally raised to 310°C with 14 °C/min and kept for 10 min. After each run a column
157 backflush was used, in order to avoid column contamination. The mass spectrometer was operated
158 in electron ionization mode, with an electron energy of 70 eV, and a mass range of m/z 50-550 and
159 a scan range of 5 spectra/sec. Single compound concentration calculations were based on the
160 relative response for each compound (compound response area/ISTD compound response area) and
161 linear calibration using eight concentration levels (0, 10, 25, 50, 100, 200, 300 and 500 ng/mL).
162 Identification of single PAH compounds was based upon 3 digit accuracy mass to charge values
163 (m/z) (Table 1) and retention times and the PAH content was quantified by calculating the relative
164 response from single compounds using calibration curves.

165 **2.5. Method validation**

166 For method validation two series of raw barley, one serie with salmon and one serie with trout, each
167 serie with four replicates at each of three concentration levels (0.5, 1 and 4 μ g/kg), were prepared
168 and analysed for the content of 15 PAHs. Before calculation of validation parameters results were
169 corrected with content in matrix blind samples (levels in Table 2 and supplementary material Tabel
170 A.2). The validation parameters included linearity, the limit of detection (LOD), limit of
171 quantification (LOQ), recovery, repeatability (SD_r) and in-house reproducibility (SD_R) according to
172 ISO 17025 (ISO/IEC 17025:2005). The LOD and LOQ were calculated according to ISO 5725-2
173 (1995) using three times and six times the relative standard deviation for the low concentration level
174 (0.5 μ g/kg). Recoveries were calculated for each matrix and spike level by dividing the detected
175 single compound concentration with the theoretical spiked concentration and multiplied by 100.
176 The relative repeatability standard deviation (RSD_r) and the relative in-house reproducibility
177 standard deviation (RSD_R) was calculated for each concentration level (0.5, 1.0 and 4.0 μ g/kg) from
178 the series of fish and raw barley, respectively according to ISO 5725-2 (1995). The series were
179 prepared on different days and calculations were made by using single sided varians analysis. A
180 FAPAS proficiency test material 0668 based on smoked fish (FAPAS 2016) was used for
181 evaluation of the trueness of the new method analysing 3 replicates (1g material each) for 6 PAH
182 compounds (BaA, CHR, BbF, BaP, BghiP, IND).

183 **3. Results and discussion**

184 The modified QuEChERS method with a non-buffered extraction salt ($MgSO_4$ and NaCl) and
185 zirconium based dispersive (Z-sep⁺) clean-up was validated for 15 PAHs in raw fortified fish (0.6
186 and 12 % fat) and fortified raw barley (dry matter 91%). The values for 4 PAHs, namely BaA,
187 CHR, BbF and BaP are reported. Additional results (other 11 PAH) can be found in the
188 supplementary material with detection parameters named Table A.1, validation results for fish and
189 raw barley (Supplementary material Table A.2), respectively and the additional 11 PAH in 5 Fish
190 and 9 Malt samples as Table A.3.

191 3.1. Method validation

192 The linearity of the calibration curves were tested for all 15 single PAHs. All calibration curves had
193 a determination coefficient (R^2) above 0.99. Linear graphic inspection as well as non-systematic
194 residual plots confirmed the linear correlation (data not shown).

195
196 For validation of fish, salmon (12% fat) and trout (0.6% fat) were fortified and analysed using 4
197 replicates at each of 3 concentration levels. The average recovery of the 4 PAHs in the fortified fish
198 samples was found to be 89-117 % for spike levels of 0.5, 1.0 and 4.0 $\mu\text{g}/\text{kg}$ (Table 2). Recoveries
199 between 50 and 120 % are generally accepted for the 4 PAHs in food with maximum limits (EC
200 2007). All our average recoveries for BaA, CHR, BbF and BaP was within the acceptance criterion.
201 For the total 24 spiked fish samples, recovery values ranged between 83-108% for BaA, 100-123%
202 for CHR, 86-111% for BbF and 93-111% for BaP (data not shown). These values indicated an
203 acceptable recovery for all samples of the method. In comparison, our traditional method had
204 slightly lower, however very similar recoveries between 73 and 106 % for the two lowest spike
205 levels (Duedahl-Olesen *et al.*, 2010). Previously, lower recoveries for the 4 PAHs on salmon and
206 mackerel by QuEChERS of 56-96 % (Forsberg, N.D. *et al.*, 2011) and of 87-99 % (Ramalhose,
207 M.J. *et al.*, 2009) have also been reported. For comparison, we generally do not accept recoveries
208 below 70% in our laboratory. For other PAHs than PAH4, only ANT at spiked fish concentration
209 1.0 $\mu\text{g}/\text{kg}$ had average recoveries large than 120%, namely 121% (Supplementary material Tabel
210 A.2 Fish). These values indicated acceptable recoveries for all 15 PAHs in fish.

211
212 The relative repeatability standard deviation, RSD_r and the relative in-house reproducibility
213 standard deviation, RSD_R , for the 4 PAHs in fortified fish were between 2.6 and 9.4 % (Table 2)
214 and at acceptable levels well below 22% (EC 2007). Other 11 PAHs had RSD_r and RSD_R values
215 between 2.2 and 73%, with unacceptable levels for ACY ($\text{RSD}_r = 27\%$ and 24% and $\text{RSD}_R = 68\%$
216 and 25%), ACN ($\text{RSD}_R = 73\%$ and 23%) and PHE ($\text{RSD}_R = 30\%$) (Supplementary material, Table
217 A.2 Fish).

218
219 The LOD for the 4 PAHs were below the maximum LOD of 0.3 $\mu\text{g}/\text{kg}$ required by the EU
220 regulation (EC 2007). Namely 0.07-0.12 $\mu\text{g}/\text{kg}$ (Table 2) and LOQ's were 0.14-0.24 $\mu\text{g}/\text{kg}$ (Table
221 2) for fish. The results were slightly lower than LOD values for the 4 PAHs of 0.2 $\mu\text{g}/\text{kg}$ obtained
222 in the same laboratory with PLE followed by GPC and SPE clean-up for fish (Duedahl-Olesen *et al.*,
223 2010). Our low LOD's were similar to other studies using QuEChERS method for PAH
224 analysis in e.g. horse mackerel with LOD's of 0.04-0.09 $\mu\text{g}/\text{kg}$ (Ramalhose, M.J *et al.*, 2009). Five
225 of 11 other PAHs had LOD's above the required 0.3 $\mu\text{g}/\text{kg}$ for PAH4 in the European Regulation
226 (EC 2007). These higher levels were found for ACN (0.77 $\mu\text{g}/\text{kg}$), ACY (0.71 $\mu\text{g}/\text{kg}$), PHE (0.43
227 $\mu\text{g}/\text{kg}$) and BghiP (0.35 $\mu\text{g}/\text{kg}$) (Supplementary material Table A.2 Fish).

228
229 Background levels from fish generally resulted in higher concentrations for salmon compared to
230 cod (data not shown). For PAH4 in fish background concentrations were all below LOD (Table 2).
231 Background concentrations above LOD were found for PHE (1.1 $\mu\text{g}/\text{kg}$) followed by ACY (0.98
232 $\mu\text{g}/\text{kg}$), ANT (0.67 $\mu\text{g}/\text{kg}$), FLU (0.35 $\mu\text{g}/\text{kg}$) and FLA (0.15 $\mu\text{g}/\text{kg}$), whereas compounds such as

233 ACN (0.60 $\mu\text{g}/\text{kg}$) had high background concentration levels close to but below the calculated LOD
234 (Supplementary material Table A.2 Raw barley). A large variation in concentration data due to high
235 background concentrations results in unacceptable RSD_T and RSD_R levels (ACY, ACN and PHE) at
236 low spike concentrations (0.5 and 1.0 $\mu\text{g}/\text{kg}$) as well as high LOD's (ACN, ACY, PHE, BghiP).

237

238 For evaluation of the trueness of the new method, triplicate analysis of a FAPAS proficiency test
239 material based on smoked fish (FAPAS 2016) was analysed. The 6 PAH average recoveries ($n = 3$)
240 were 46% for BaA (assigned value 31.2 $\mu\text{g}/\text{kg}$), 71 % for BaP (assigned value 12.6 $\mu\text{g}/\text{kg}$), 94% for
241 CHR (assigned value 31.4 $\mu\text{g}/\text{kg}$), 104 % for B(ghi)P (assigned value 7.08 $\mu\text{g}/\text{kg}$), 111% for BbF
242 (assigned value 14.8 $\mu\text{g}/\text{kg}$) and 120% for IND (assigned value 6.63 $\mu\text{g}/\text{kg}$). Only the trueness for
243 BaA was unacceptable (below 70%). The accuracy (precision and trueness) of the new method in
244 fish is therefore acceptable for CHR, BkF and BaP, whereas only precision where acceptable for
245 BaA. Indications of BaA signal suppression will be discussed under discussion of figure 1.

246

247 For validation of raw barley, two series with 4 replicates at each of three concentration levels (0.5;
248 1.0; 4.0 $\mu\text{g}/\text{kg}$) were used. The average recoveries for the 4 PAHs were 88-111 % (Table 2).
249 Generally, recoveries for BaP, BbF and BaA ranged from 73-110%, 76-104% and 85-110%,
250 respectively (data not shown) and therefore were acceptable for all replicates. For CHR the average
251 recoveries were between 105 and 111% (Table 2), with recoveries ranging from 93 to 128% for the
252 24 replicates. Recoveries for cereals analysed by QuEChERS has been reported to be similar to our
253 results, namely between 86-91 % for the 4 PAHs (Kacmaz *et al.*, 2016). Our results therefore
254 indicate good recoveries for the 4 PAHs, however for the other 11 PAH compounds, a large average
255 recovery range was obtained. Especially ACY (121%), PHE (134%), ANT (132%) and PYR
256 (127%) had recoveries above 120% at the lowest spike level (0.5 $\mu\text{g}/\text{kg}$). PHE (124%) and ANT
257 (142%) also had recoveries above 120% for spiked concentration levels of 1 $\mu\text{g}/\text{kg}$ and ANT
258 (147%) also at high spiked level at 4.0 $\mu\text{g}/\text{kg}$ (supplementary material A.2 Raw barley).

259

260 The relative repeatability standard deviation, RSD_T and the relative in-house reproducibility
261 standard deviation on different days, RSD_R , in fortified raw barley were between 2.7 and 16 % for
262 the 4 PAHs (Table 2) indicating that the QuEChERS method is precise for cereals. For the other 11
263 PAHs RSD_T and RSD_R values were found to be between 2.1 and 49%, only with acceptable levels at
264 all spiked concentrations for FLA, PYR, BkF, DBahA, and IND (Supplementary material A.2 Raw
265 barley). Only BbF, BaA, CHR, BaP, BkF, FLA, and IND had acceptable recoveries as well as
266 acceptable RSD_T and RSD_R levels when comparing to criterion for matrices with EU maximum
267 limits (EC 2007). These results were similar to results reported by Kacmaz *et al.* with RSD_T and
268 RSD_R values between 5.4-17.0% for cereals.

269

270 The LOD for the 4 PAHs in barley was 0.06-0.12 $\mu\text{g}/\text{kg}$ and LOQ values were between 0.12 and
271 0.24 $\mu\text{g}/\text{kg}$ (Table 2). These detection limits were more than twicethe LOD's previously reported
272 for cereals (0.01-0.03 $\mu\text{g}/\text{kg}$) by Kacmaz *et al.* using n-hexane and cyclohexane for QuEChERS
273 (Kacmaz *et al.*, 2016). Their results indicated that lower detection limits might be obtained by
274 exchange of solvents. However, preliminary experiments on spices using n-hexane resulted in high

275 concentrations of ethereal oils making the final extract impossible to apply for GC analysis (data
276 not shown). Also, Cloutier *et al.* indicated that acetonitrile was inefficient for QuEChERS
277 extraction of PAH in fatty samples (Cloutier, P-L. et al., 2017), which could be the reason for the
278 obtained low trueness of BaA in the reference material (FAPAS). Our validation results however,
279 indicated that not all PAH compounds were affected by the use of acetonitrile. Detection limits
280 above 0.3 $\mu\text{g}/\text{kg}$ and at higher levels than validation of fish were obtained for FLU (1.4 $\mu\text{g}/\text{kg}$),
281 PHE (0.57 $\mu\text{g}/\text{kg}$), BghiP (0.39 $\mu\text{g}/\text{kg}$) and ANT (0.36 $\mu\text{g}/\text{kg}$).

282
283 Similar to fish validation, background levels from barley resulted in concentrations above LOD for
284 ANT (3.8 $\mu\text{g}/\text{kg}$), ACY (1.8 $\mu\text{g}/\text{kg}$) and PHE (1.4 $\mu\text{g}/\text{kg}$) (Supplementary material Table A.2 raw
285 barley). FLU (0.75 $\mu\text{g}/\text{kg}$), ACN (0.40 $\mu\text{g}/\text{kg}$), FLA (0.36 $\mu\text{g}/\text{kg}$), PYR (0.33 $\mu\text{g}/\text{kg}$), and BaP (0.10
286 $\mu\text{g}/\text{kg}$) were also found in high background concentrations (Table 2 and supplementary material
287 Table A.2 raw barley). These high background concentrations resulted in a large data variation and
288 especially unacceptable RSD_R levels (ACY, ACN, FLU, PHE, ANT and BghiP) at low spike
289 concentrations (0.5 $\mu\text{g}/\text{kg}$) as well as high LOD's (Supplementary material Table A.2 raw barley).

290 Due to the challenges on single PAHs in both fish and raw barley the chromatograms were studied
291 further. Figure 1a shows a chromatogram for standard 25 ng/ml for BaA and CHR with a fortified
292 cod (1.0 $\mu\text{g}/\text{kg}$) in Figure 1b. In Figure 2a, the standard 25 ng/ml for BbF and BaP is shown and a
293 spiked barley (1.0 $\mu\text{g}/\text{kg}$) in Figure 2b. Spiked levels at 1.0 $\mu\text{g}/\text{kg}$ correspond to a level of 25 ng/ml.
294 Both matrices seem to result in matrix effects. In Figure 1b an enhanced signal seems to be obtained
295 when matrix is included, however no interferences or suppression for BaA seems to be visible ($\text{rt} =$
296 20.7 min). For the reference material (FAPAS) a lower signal than expected for BaA was visible
297 without interfering peaks. However, for FAPAS, an increased baseline was identified when
298 comparing the full scan chromatogram to that of fortified fish (data not shown). The low BaA
299 recovery for the smoked fish in the FAPAS material indicate a non-identified signal depression for
300 BaA in smoked material compared to non-smoked. The used reference material (FAPAS) also
301 included concentration levels approximately ten times higher than the EU maximum limits and
302 therefore levels not previously studied by fortification etc. To study the phenomenon further, a
303 matrix-matched calibration curve based on smoked fish could be analysed. In Figure 2b for barley,
304 be matrix suppression as well as several interfering peaks is visible.). The interferences was first
305 expected to be due to the solid extraction material (salt and SPE), however a reagent blank (no
306 matrix) revealed no carry over from the used material (solvents, salts and dispersive SPE) to the
307 chromatograms of the detected single PAHs (data not shown). The use of a corresponding internal
308 standard for each of the PAHs and use of relative responses minimize the influence of these matrix
309 effects on our results. The zirconium clean-up step has previously been deemed relevant for
310 challenged matrices (Al-Thaiban et al., 2018), however due to our results dried low fat material
311 such as barley as well as smoked fish might be even more challenging. It was not possible to obtain
312 cereal based reference material for evaluation of trueness for barley.

313 **3.2 Concentration of PAH in smoked fish and malt**

314 The developed QuEChERS method was used to determine PAH4 in processed food products
315 similar to the validated matrices, namely fish and malt. Focus was on different smoking techniques

316 such as hot and cold smoked salmon, as well as the heat source (e.g. beech and alder) (Table 3).
317 After cold smoked salmon (PAH4 < 0.34 µg/kg), the alder wood hot smoked salmon (PAH4 = 0.69
318 µg/kg) contained the lowest concentrations of PAH4, whereas beech wood hot smoked salmon had
319 PAH4 concentrations of 1.1 µg/kg. Beech wood hot smoked mackerel had the highest PAH4
320 concentration (2.15 µg/kg), whereas beech wood hot smoked herring only contained 0.55 µg/kg.
321 Our results with higher PAH4 levels in hot smoked compared to cold smoked salmon are similar to
322 previously reported results for smoked fish products (Duedahl-Olesen *et al.*, 2010). However, for
323 both BaP and PAH4 our results are well below the EU maximum limit of 2 µg/kg and 12 µg/kg,
324 respectively (EC 2006). ACY and ANT were found in highest concentrations and at levels up to 27
325 µg/kg in beech wood hot smoked fish compared to cold smoked fish (up to 1.4 µg/kg) and alder
326 wood smoked fish (up to 12 µg/kg) (Supplementary material Table A.3). These results could
327 indicate a mitigating action at fish mongers on PAH levels when applying hot smoking procedures.
328 ACY and ANT are not included in the 15+1 PAHs considered to affect the human health and might
329 be omitted for control of matrices complying with the EU regulation. Our results on different
330 smoking conditions are however not as clear as Duedahl-Olesen *et al.*, due to the use of too few
331 samples. More samples should be included for verification of a trend towards lower PAH4 levels in
332 smoked.

333
334 Nine malt samples were analysed, four were smoked with beech or peat (Table 3). The sum of
335 PAH4 varied widely depending on the malt type. The amount of PAH4 in smoked malt was found
336 to be highest for peat smoked malt (15 and 26 µg/kg), followed by beech smoked malt (1.0 and 0.9
337 µg/kg) with nonsmoked malt PAH4 levels below LOD (Table 3). The latter results were similar or
338 even lower than the concentrations found by Kazmac *et al.* of 0.23 - 0.87 µg/kg in cereal based
339 breakfast products (Kazmac *et al.*, 2016). Furthermore, a small amount of IND was detected in all
340 malt samples and not in the fish samples (supplementary material Table A.3). For malt samples the
341 dominating PAHs were ACY and FLU with concentration levels ranging from 0.6 µg/kg in raw
342 barley to 25 µg/kg in peat smoked barley and from <1.5 µg/kg in beech smoked barley to 91 µg/kg
343 in raw barley, respectively. In comparison malt and beech smoked barley had high concentration
344 levels of FLU whereas peat smoked barley also had high concentrations of BaA, BbF and BaP
345 (Table 3) as well as ACY, PHE, ANT, FLA and PYR (Supplementary material Table A.3).

346
347 Due to the slightly variable validation results we conclude that the QuEChERS method should only
348 be used for screening with further verification of results close to maximum EU limits. Screening for
349 EU maximum limits includes four PAHs, namely BaP, BaA, CHR and BbF. All these compounds,
350 were within acceptable ranges for the precision and robustness of the method. The validation
351 described in this study illustrates that it is necessary to validate the method for new PAHs as well as
352 matrices before inclusion of these in the method. Method validation for fish revealed nonacceptable
353 precision for ACN, whereas for barley ACY, ANT, PHE and PYR precisions were nonacceptable.
354 More purifications steps could be included in the method to avoid matrix enhancement (fish) or
355 matrix suppression (barley and malt) resulting in more time-consuming sample preparation.. This
356 was however not the goal for our screening method and we suggest that further method development

357 of QuEChERS could include exchange of salts, solvents, dispersive SPE material and application of
358 matrix-matched calibration curves for improved BaA trueness in smoked fish.
359

360 **4. Acknowledgment**

361 We would like to thank Helen Fodnæs for English proof reading and Mikael Pedersen for
362 discussions on method validation.

Figure 1

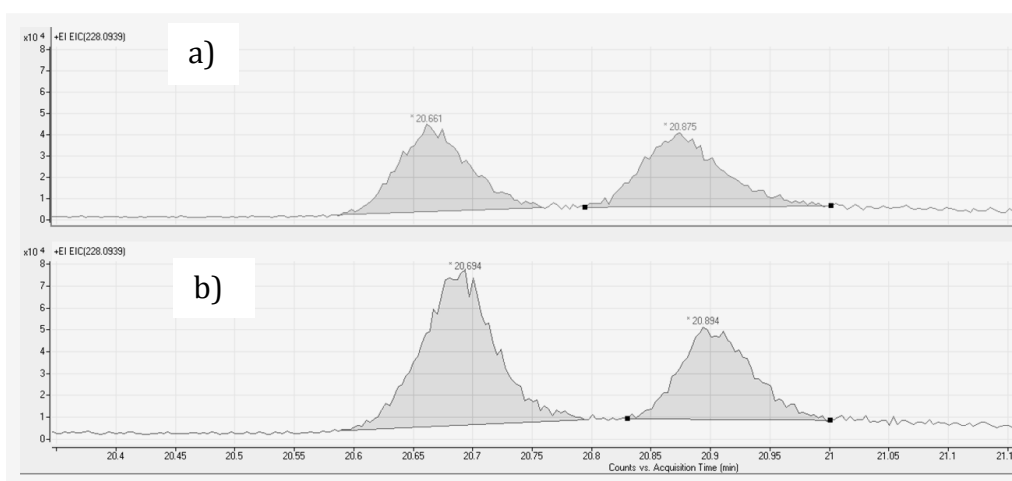

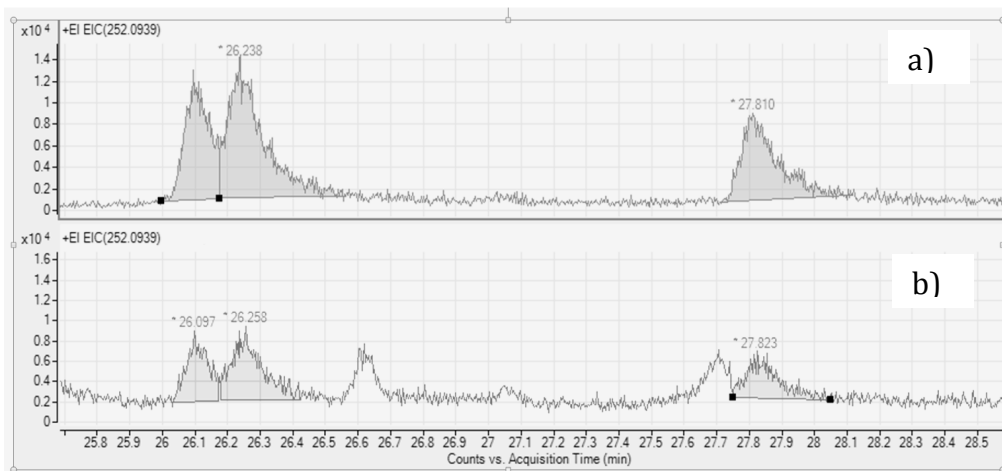

Figure 2

Highlights:

- Successful validation of QuEChERS screening method for PAH4 analysis.
- PAH4 average recoveries between 93 and 117 % with LOD's below 0.12 $\mu\text{g}/\text{kg}$.
- Peat smoked malt contained high PAH4 levels ranging from 15 to 36 $\mu\text{g}/\text{kg}$.
