Overview of Bluetongue in Denmark 2008

Background
The first case ever of bluetongue (BT) in Denmark was recorded in October 2007, so the biting midge season in spring 2008, was awaited with some anxiety, due to the rapid spread of the BTV serotype 8 epidemic in the countries south of Denmark.

First outbreak in 2008
The first outbreak in Denmark 2008 was detected on August 27 in a cattle herd in Bredebro, which is located in the southern part of Denmark, approximately 20 km north of the German border. Initially two animals were suspected of having BT based on clinical symptoms so EDTA blood and serum samples were submitted to our laboratory. One of the animals tested positive by ELISA (OD 0.56: 1:4) and real time PCR (Ct 27.1 0.6).

To evaluate the extent of this outbreak it was decided to use the remaining animals in pools from 5 samples.

Three pools were found positive for BT virus (BTV) by real time PCR. In each of these pools one sample of the five was positive for BTV RNA.

The animals were also tested individually for the presence of antibodies against BTV by ELISA. Of the 75 animals tested, 15 were found positive for BT specific antibodies. Of these 24 were cattle and the rest were sheep. The three PCR positive cows had high levels of anti-BTV antibodies (ODs 4.32 2.87) whereas the 21 antibody positive but PCR negative cows had lower levels of antibody (ODs 0.30 0.49).

The latter results are probably due to the fact that vaccination against BTV took place 9 days prior to the collection of blood and several animals had seroconverted in the intervening days.

Vaccination experiment
The clinical symptoms of the first herd were observed in connection with vaccination against BT and the blood, from the two first animals, submitted for confirmation was sampled again, 90 min after vaccination, which raised the question of whether the positive PCR results could be due to the vaccine.

In order to address this issue, a study was performed in which blood samples were collected at short time intervals immediately before vaccination until 90 min after vaccination (sampling times: 0-25, 1, 4, 24, 48 and 96 h).

Serotyping & sequencing
Bluetongue virus from all outbreaks were screened by real time PCR (TaqP BVTV9, LIS, Lusignan, France) and found to be BTV 8.

Sequencing of a part of segment 2 (using primer set FIV(2) was performed on BTV RNA from three outbreaks which were believed to be representatives of all outbreaks. The most northern (Skjern, 08.09.2008), the most southern (Tønder 09.09.2008) and the first outbreak (Bredebro, 27-08-2008). See map for the date for geographic location.

Sequences were identical from all three outbreaks and had 100% homology with the BTV8 sequences circulating in Finland in 2006.
