## 1. Introduction

Radio-over-Fiber (RoF) technology is very attractive for implementing seamless wireless access services in future networks, which is to consolidate different types of services into a homogenous infrastructure with compact network size and less connection complexity [1]. Traditionally, expensive radio-frequency (RF) down-conversion technology is necessary in the RoF transmission system. A more cost-effective RoF communication system with simple access nodes is therefore expected, as well as symmetric broadband wireless services. Recent research has shown that optical envelope detection techniques, without RF oscillator and mixer, satisfactorily perform reception of RoF signals [2, 3]. On the other hand, reflective semiconductor optical amplifier (RSOA) operating as a modulator at an optical network unit (ONU) is a promising component to implement a bidirectional system because of its attractive features related to its multi-functionalities of optical amplifier and modulator [4-6]. Very recently, we have also proposed a bidirectional RoF system with phase modulation uplink and oscillator-free downlink by employing an RSOA, which acts simultaneously as an intensity modulator and an optical envelope detector [7]. In this paper, we exploit and evaluate the extension of the system performance, by using the colorless operation of the RSOA to build effective, bidirectional, wavelength division multiplexing (WDM) system with high wavelength utilization and improved capacity.

Fig. 1 depicts the network topology of WDM RoF wireless access networks by employing RSOAs. A central office is composed of a laser array with  $n$  laser diodes (LDs) which offers WDM wavelengths for downlink, a receiver array to demodulate uplink signals from ONUs, a phase modulator (PM) array to impose electrical information into optical carrier signal, and two arrayed waveguide gratings (AWGs) operate as a wavelength multiplexer and a demultiplexer. A circulator is used to separate the WDM downstream transmitters and upstream channels. At the remote node after fiber transmission, another AWG is employed to separate the WDM downstream channels and combine the upstream channels. Each ONU includes a downstream receiver and a RSOA.

In this paper we experimentally demonstrate a RSOA based WDM bidirectional RoF transmission system. The multi-functionalities of RSOA, such as colorless operation, re-modulation and envelope detection, lead to no need of RF down-conversion and laser source for the uplink, and make the wireless access nodes simple and compact.

## 2. Experimental Setup and Operation Principle

The proof-of-concept experimental setup is shown in Fig. 2. Two lights from two external cavity lasers (ECL1 and ECL2) with wavelengths of 1555 nm and 1553.8 nm are combined at a 3 dB coupler, and then phase modulated at 5.25 GHz RF carrying 850 Mbps data with pseudo random binary sequence (PRBS) length of  $2^9-1$ . The optical spectra for downstream signals after the phase modulator is shown in Fig.3 (a), and we state that channel 1 (Ch1) is at 1555 nm wavelength, and channel 2 (Ch2) is at 1553.8 nm. This two-channel downstream signal is launched into 25 km of standard single mode fiber (SSMF) with a 5 dB insertion loss. At the output of the fiber, another 3dB coupler is used to split the downstream signals. Half the signals proceed to the downstream receiver, and the other half are routed to the RSOA at upstream transmitter for wavelengths reuse as the upstream signals. At the downstream receivers the optical signals are amplified by an Er-doped fiber amplifier (EDFA) and the EDFA noise is rejected using an optical bandpass filter with a 3dB bandwidth of 0.4 nm. An imbalanced-path Mach-Zehnder interferometer (MZI) performs the function of optical self-heterodyning to translate the phase encoded information to intensity information. A MZI with a frequency response period of 10.7 GHz is used in the experiment. After balanced photodetection, the signal is down-converted by using a 1.8 GHz electrical lowpass filter (LPF) and is subsequently fed to an error detector for bit error rate (BER) measurements on the downstream signal. By tuning the phase offset between the two arms of the MZI, the signal after photodetection is composed of both a down-converted baseband component and higher order frequency components containing the complete RoF signal [9]. At the upstream transmitter, a 10 GHz RF signal carrying 850 Mbps data with length of  $2^9-1$  is used to drive the RSOA biased at 1.4 V DC. Lights from the phase modulated downlink signals are intensity modulated and reflected by the RSOA, therefore the downstream and upstream channels share the same wavelength and optical source. The reflective upstream signals are then transmitted in the reverse direction over 25 km of SSMF and detected by an upstream receiver, which consists of an EDFA, an optical bandpass filter (OBPF), an attenuator and a photodiode.

In this system, the RSOA firstly performs high-wave rectification by the choice of the bias. Secondly, due to the modulation speed limitation it performs simultaneously the envelope detection (allows only the baseband frequency components within the electrical bandwidth of RSOA). As shown in Fig. 3 (b), when the 850 Mbps bit rate at 10 GHz RF is applied to RSOA (1.5 GHz bandwidth), no RF components are observed on a scope detecting the reflective optical signal, and only the 850 Mbps digital signal is recovered. The RSOA therefore performs not only the function of optical intensity modulator, but also the function of envelope detection, which leads to no need of microwave components, such as RF mixer and local oscillator.

(b) The electrical 10GHz RF carrying 850Mbps data driving the RSOA at the upstream transmitter, Horizontal scale: 2ns/div, Vertical scale: 560mV/div. (c) The recovered electrical signal on a scope from driving signal (a) Horizontal scale: 5ns/div, Vertical scale: 56mV/div.

### 3. Experimental Results and Discussions

The BER curves for both downstream channels are displayed in Fig.4 (a). All the cases are measured after 25 km fiber transmission with the co-propagation of upstream signals. The results indicate that the Ch1 downstream receiver sensitivities at a BER of  $10^{-9}$  are around -24.5 dBm and -21.5 dBm for the cases with and without Ch2 downstream signals, respectively. For the Ch2 downstream signals, the downstream receiver sensitivities with and without the co-propagation of Ch1 are found to be about -23.0 dBm and -20. dBm. Fig.4 (b) shows the measured BER performances for 2-channel upstream signals after 25 km SSMF transmission, as well as with and without the co-propagation of the neighbor channel. We can notice from Fig.4 (b) that when two channels are transmitted simultaneously, both channels (Ch1 and Ch2) have same receiver sensitivities of -12 dBm. In the cases of one-channel transmission, the receiver sensitivities for Ch1 and Ch2 are about 14 dBm and -15 dBm, respectively.

For either downstream or upstream channels, we can notice that the co-propagation of second channel introduces about 3 dB sensitivity penalty. Limited by the 18 dB rejection of OBPF at 1.2 nm bandwidth, the crosstalk caused by the Rayleigh backscattering from the neighbor channel degrades the receiver sensitivity [8]. On the other hand, the performances of the upstream signals are also related to the gain and noise figure of the RSOA. Actually, the RSOA used in the experiment performs the functions of not only an intensity modulator and an envelope detector, but also an optical amplifier. The amplified spontaneous emission (ASE) noise decreases the signal-to-noise ratio of the upstream signal. As shown in the inserted eye diagrams in Fig.4, the eye diagram of downstream signal is cleaner than that the upstream signal.

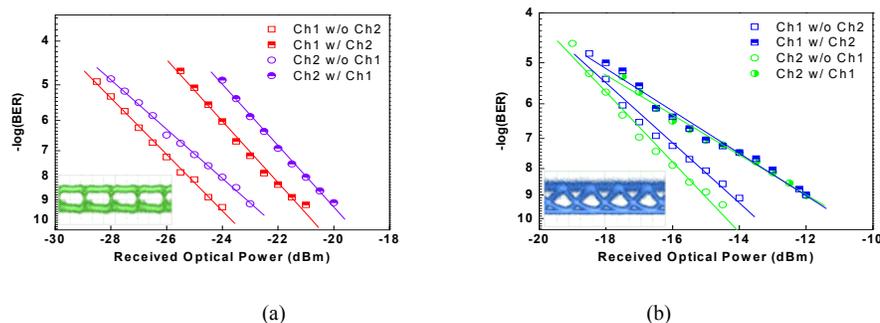

Fig. 4. The measured BER curves of two-channel (a) downstream and (b) upstream RoF signals after 25 km fiber transmission.

### 4. Conclusions

We propose and experimentally demonstrate a WDM bidirectional RoF network with compact wireless access nodes. Contributed to the multi-functionalities of RSOA, no laser source and RF down conversion are needed for the uplinks. In the experiment, in order to separate the transmitted RoF signals at the same wavelength, phase modulation and intensity modulation are used for downstream and upstream signals, respectively. The experimental results show that all channels for both 850 Mbps at 10 GHz RF upstream and 850 Mbps at 5.25 GHz RF downstream signals are error-free after 25 km SSMF transmission. Therefore, the proposed system offers a good solution for next generation optical wireless access network.
