(Received 18 March 2005; revised 22 July 2005; accepted 16 November 2005)

This work is related to modeling of synthetic sonar images of naval mines or other objects. Considered here is the computation of high frequency scattering from the surface of a rigid 3D-object numerically represented by plane triangular facets. The far field scattered pressure from each facet is found by application of the Kirchhoff approximation. Fawcett [J. Acoust. Soc. Am. 109, 1319–1320 (2001)] derived a time domain expression for the backscattered pressure from a triangular facet, but the expression encountered numerical problems at certain angles, and therefore, the effective ensonified area was applied instead. The effective ensonified area solution is exact at normal incidence, but at other angles, where singularities also exist, the scattered pressure will be incorrect. This paper presents a frequency domain expression generalized to bistatic scattering written in terms of sinc functions; it is shown that the expression improves the computational accuracy without loss of robustness. © 2006 Acoustical Society of America.

I. INTRODUCTION

In the past decade low price hardware has made high frequency sonar imagery systems widely available for naval-mine identification, harbor surveillance, and offshore industry. This work is related to the generation synthetic sonar images of naval mines and other objects.

An object will be numerically represented by elementary facets. The far field scattered pressure from each facet is found by application of the physical optics solution or Kirchhoff approximation.1,2 The total scattered field is given as the coherent sum of pressure contributions from all nonshadowed facets.

The plane rectangular facet has been used by Sammelmann3 and George.4 However, for arbitrarily shaped objects the plane rectangular facet can lead to problems concerning correct surface representation. The plane triangular facet, on the other hand, is suited for all types of surfaces because of its co-planar property. Fawcett5 derived the time domain impulse response for backscattering from a plane triangular facet. An alternative to the flat facet approach is the application of nonuniform rational B-spline surfaces (NURBS).6 The field integral is evaluated over a parametric space of Bezier surfaces using the method of stationary phase.

The plane triangular facet is considered in this note. The expression for the scattered pressure from the plane triangular facet, first presented by Fawcett,5 consists of three contributions corresponding to a response from each of the three vertices. However, this vertex response, which is applicable in the time domain, becomes numerically unstable at certain angles as the angle dependent coefficients get very large due to division by very small numbers. One way to deal with this is to replace the integral solution with the effective ensonified area, when the coefficients exceed, say, 1000.5 This...
The unit surface normal vector has been transformed into

\[ \hat{n}_s = \mathbf{r}_s \cdot \mathbf{u}_s \]

where \( \mathbf{r}_s = \mathbf{r}_0 - \mathbf{r}' \) and \( \mathbf{u}_s = \mathbf{v} - \mathbf{v}_0 \). The vectors connecting the vertex points are defined by \( \mathbf{u} = \mathbf{P}_0 \mathbf{P}_1 \mathbf{P}_2 \mathbf{P}_3 \) and \( \mathbf{w} = \mathbf{P}_0 \mathbf{P}_3 \mathbf{P}_2 \mathbf{P}_3 \), and they are arranged such that \( \mathbf{u} \) represents the two longest sides of the triangle and \( \mathbf{u} \times \mathbf{v} \cdot \hat{n}_s > 0 \); see Fig. 1.

A local coordinate system (') is introduced. The origin \( \mathbf{O}' \) has the global coordinates \( \mathbf{O}' = \mathbf{O} + \mathbf{v}_0 \), where \( \mathbf{v}_0 \) is the projection of \( \mathbf{v} \) on \( \mathbf{u} \). In the local coordinate system the triangle is described by the axis-points \( x'_1, x'_2, \) and \( y'_3 \). The base of (') is

\[ \begin{align*}
\mathbf{e}'_1 &= \mathbf{u}/|\mathbf{u}|, \\
\mathbf{e}'_2 &= (\mathbf{v} - \mathbf{v}_0)/|\mathbf{v} - \mathbf{v}_0|, \\
\mathbf{e}'_3 &= \mathbf{e}'_1 \times \mathbf{e}'_2.
\end{align*} \]

The base given by Eqs. (1a)–(1c) establishes a coordinate transformation matrix applied on \( \mathbf{r}_0 \), the vector from \( \mathbf{P}_0 \) to the source, and on \( \mathbf{r}_1 \), the vector from \( \mathbf{P}_0 \) to the observation point. In the (’)-coordinate system \( \mathbf{r}_0 \) and \( \mathbf{r}_1 \) have been transformed into \( \mathbf{r}'_0 \) and \( \mathbf{r}'_1 \), respectively, but their (Euclidian) lengths are unchanged, i.e., \( |\mathbf{r}'_0| = |\mathbf{r}_0| = r_0 \) and \( |\mathbf{r}'_1| = |\mathbf{r}_1| = r_1 \). The unit sphere normal vector has been transformed into \( \hat{n}'_s = [001]^T \), and each point on the plane facet, \( S \), is given by \( \mathbf{x}'_s = [x'y'z']^T \); see Fig. 2.

The Kirchhoff approximation is applied on the rigid surface and the total pressure field, \( p \), is related to the incoming field, \( p_{inc} \), through

\[ p(x'_s) = 2p_{inc}(x'_s) \]

(see, e.g., Fawcett\(^5\)). The Kirchhoff Helmholtz integral equation [see, e.g., Pierce,\(^7\) Eq. (4.64)] consequently reduces to the integral

\[ p_{inc}(\mathbf{x}'_s) = \frac{1}{2\pi} \int_S p_{inc}(\mathbf{x}'_s) \nabla G(\mathbf{x}'_s, \mathbf{r}'_s) \cdot \hat{n}'_s dS, \tag{3} \]

where \( p_{inc}(\mathbf{r}'_s) \) is the facet-scattered pressure measured at the observation point, \( \mathbf{r}'_s \), and \( \nabla G(\mathbf{x}'_s, \mathbf{r}'_s) \) is the gradient of the free space Green’s function directed toward the observation point. The incoming field originates from a monopole source,

\[ p_{inc}(\mathbf{x}'_s) = \frac{p_0}{|\mathbf{x}'_s - \mathbf{r}_0'|} e^{ij|\mathbf{x}'_s - \mathbf{r}_0'|} \tag{4} \]

where \( p_0 \) is the pressure amplitude 1 meter from the source. In the far field, the range from the facet to the source by far exceeds the dimensions of the facet, and hence, a first order Taylor series expansion of \( |\mathbf{x}'_s - \mathbf{r}_0'| \) with respect to \( \mathbf{x}'_s / r_0 \) is possible,

\[ |\mathbf{x}'_s - \mathbf{r}_0'| \approx r_0 - \mathbf{r}_0' \cdot \mathbf{x}'_s, \tag{5} \]

where \( \mathbf{r}_0' = \mathbf{r}_0 / r_0 \) [see, e.g., Ogilvy,\(^1\) Eq. (4.10)]. The right-hand side of Eq. (5) will be applied for the phase term of Eq. (4) whereas it is sufficient to approximate the slowly varying denominator in Eq. (4), i.e., the term that represents geometrical spreading, to zero order, that is, \( |\mathbf{x}'_s - \mathbf{r}_0'| \approx r_0' \). The incoming field is

\[ p_{inc}(\mathbf{x}'_s) = p_0 e^{i\mathbf{k} \cdot \mathbf{x}'_s} e^{-ik \cdot \mathbf{r}_0'}, \tag{6} \]

and hence, the part of the spherical wave that sweeps over the facet is considered locally plane. The gradient of the Green’s function,

**II. FACET-GEOMETRY AND FIELD APPROXIMATIONS**

In this section a scattering integral for a rigid, plane and triangular facet is derived. The Kirchhoff approximation as well as the far field approximation are applied.

Suppose an arbitrarily shaped body is numerically represented by plane triangular facets. Each facet in the three-dimensional space is represented by its vertex points \( \mathbf{P}_1, \mathbf{P}_2, \mathbf{P}_3 \) and the unit surface normal vector, \( \hat{n}_s \), pointing out of the body. The Kirchhoff equa-

---

\[ \nabla G(r'_i | x'_j) = \frac{r'_i - x'_j}{|r'_i - x'_j|} (ik|r'_i - x'_j| - 1) e^{ik|r'_i - x'_j|}, \]  
\[ \nabla G(r'_i | x'_j) = \hat{r}'_i e^{ikr'_i} - \hat{r}'_i e^{-ikr'_i} x'_j, \]

where \( \hat{r}'_i = r'_i / r_i \). Insertion of Eq. (6) and Eq. (7) into Eq. (3) leads to a scattering integral with a linear phase term

\[ p_{sc}(x) = \frac{p_0 e^{ik(r_o + r'_j) \hat{r}'_i \cdot \hat{n}_i}}{2 \pi r_0 r'_i} \int_S e^{-ik(r'_i + r'_{j}) x'_j} dS. \]

### III. A ROBUST EXPRESSION FOR TRIANGULAR FACET SCATTERING

If the phase variation over the facet is neglected, the integral in Eq. (9) can be replaced by the facet area, \( S \), and the approximate effective ensonified area response is

\[ p_{sc}(x) = \frac{p_0 e^{ik(r_o + r'_j) \hat{r}'_i \cdot \hat{n}_i}}{2 \pi r_0 r'_i} S, \]

where \( \cos \theta_i = \hat{r}'_i \cdot \hat{n}_i \). However, this expression is only exact for normal incidence. In the general case the dot-product in the exponential term of the surface integral Eq. (9) must be considered,

\[ (\hat{r}'_i + \hat{n}_i) \cdot x'_j = ax' + by', \]

where the angle dependent constants are given by

\[ a = \sin \theta_0 \cos \phi_0 + \sin \theta_1 \cos \phi_1, \]
\[ b = \sin \theta_0 \sin \phi_0 + \sin \theta_1 \sin \phi_1, \]

and where the angle between \( r'_i \) and \( n'_j \) is \( 0 \leq \theta_i \leq \pi / 2 \), and the angle in the \( x' y' \) plane is \( 0 \leq \phi_j \leq 2 \pi, j = 0, 1 \). The solution to Eq. (9) is brought on the vertex form

\[ p_{sc}(x) = \frac{p_0 e^{ik(r_o + r'_j) \hat{r}'_i \cdot \hat{n}_i}}{4 \pi r_0 r'_i} \left[ \frac{\kappa_1 e^{-ikx'_j} + \kappa_2 e^{-iky'_j}}{ik2 r_0 r'_i} \right], \]

where \( \kappa_1, \kappa_2 \), and \( \kappa_3 \) are the vertex coefficients given by

\[ \kappa_1 = \frac{-y'_j}{a(ax'_1 - by'_j)}, \]
\[ \kappa_2 = \frac{y'_j}{a(ax'_1 - by'_j)}, \]
\[ \kappa_3 = \frac{y'_j(x'_j - x'_1)}{(ax'_2 - by'_j)(ax'_1 - by'_j)}. \]

The vertex response can be transformed into the time domain to obtain the impulse response (see, e.g., Fawcett). As can be observed from Eqs. (13b)–(13d) three singularities are present, \( a = 0 \), \( ax'_1 - by'_j = 0 \), and \( ax'_1 - by'_j = 0 \). For backscattering these singularities correspond to incident directions normal to the three sides of the triangle, i.e., normal to \( u, w \) or \( v \). From an analytical point of view, large values of \( \kappa_i \) will cancel each other in Eq. (13a). However, in a numerical implementation the cancellation tends to fail because of truncation errors obtained near the working precision of the computer. In what follows the time domain approach is abandoned and a numerically robust expression is derived. The angle dependent terms \( a, (ax'_1 - by'_j), \) and \((ax'_1 - by'_j)\) are separated and expressed in terms of the well-behaved sinc function. Hence, the solution to Eq. (9) is written

\[ p_{sc}(x) = \frac{p_0 e^{ik(r_o + r'_j) \hat{r}'_i \cdot \hat{n}_i}}{2 \pi r_0 r'_i} \left[ \frac{1}{ikb} \times \left[ x'_i e^{-ikax'_1} + by'_j \right] \frac{\sin(k[ax'_1 - by'_j]/2)}{k[ax'_1 - by'_j]/2} \right. \]
\[ - \left. x'_i e^{-ik(ax'_1 + by'_j)/2} \frac{\sin(k[ax'_1 + by'_j]/2)}{k[ax'_1 + by'_j]/2} \right] \]
\[ + \left( x'_i - x'_j \right) e^{-ik(ax'_1 + by'_j)/2} \frac{\sin(ka[x'_i - x'_j]/2)}{ka[x'_i - x'_j]/2}. \]

When \( b \rightarrow 0 \), Eq. (14a) becomes numerically unstable, and is replaced by the limit value, \( p_{sc}(x) \) for \( b \rightarrow 0 \), found by using the rule of L'Hospital,

\[ p_{sc}(x) = \frac{p_0 e^{ik(r_o + r'_j) \hat{r}'_i \cdot \hat{n}_i}}{4 \pi r_0 r'_i} \left[ \frac{g(kax'_j/2)x'_i e^{-ikx'_j/2}}{x'_i} \right. \]
\[ - \left. g(kax'_j/2)x'_i e^{-ikx'_j/2} \right], \]

where

\[ g(x) = -\frac{\cos(x) + \sin(x)/x}{x} - i \times \frac{\sin(x)}{x}. \]

### IV. RESULTS

Validation is carried out by considering the canonical problem of backscattering of a plane wave of unit amplitude from a rigid sphere. The infinite harmonic series solution is the Benchmark solution. The sphere is a good test case because sharp edges, where the Kirchhoff approximation fails, are absent. The time domain response of a 445 kHz Ricker pulse incident on a sphere with a radius equal to 10 centimeters measured at a range of 10 meters is determined. In the numerical model the surface of the sphere is represented by iso-sized facets with areas of 11 mm². Results from three different numerical Kirchhoff approaches are considered. The first approach is the vertex response given by Eqs. (13) where no numerical precautions are taken. In the second approach the vertex response is combined with the effective area response given by Eq. (10) according to Fawcett. The vertex response is switched “off” and the effective area response “on” when the magnitude of one of the coefficients in Eqs. (13) exceed 1000. Finally, the third ap-
The robust response given by Eq. (14) matches the analytic solution very well except after the specular reflection where oscillations occur. These oscillations are related to the numerical surface discretization of the sphere and not the scattering formulas. The result from the pure vertex response, Eqs. (13), clearly diverges from the analytical solution at the specular reflection, but after that, it quickly approaches the robust response. Hence, the pure vertex response is accurate as long as the critical angles are not encountered; if this happens, erroneous results orders of magnitude from the actual response will occur. The combined solution is significantly closer to the analytical result at the specular reflection, but exhibits stronger oscillations after the specular reflection, indicating that the combined approach is a robust, but not very accurate, numerical approach when singularities are encountered. The robust response expressed in terms of sinc functions has proven to be the most numerically reliable expression.

V. CONCLUSION

A numerically robust expression for the far field bistatic scattered pressure from a plane triangular facet written in terms of sinc functions, Eq. (14), has been presented. The expression is applied for the computation of high frequency scattering from arbitrarily shaped objects. Equation (14) has been compared with two solutions based on the vertex response expression, Eq. (13). The first solution is the pure vertex response which is numerically unstable at certain angles. The second solution, presented by Fawcett, combines Eq. (13) with the effective ensonified area, Eq. (10), in the case where one of the coefficients of the vertex response, Eqs. (13b)–(13d), exceeds a threshold value equal to 1000. Comparisons have been carried out by considering the canonical problem of backscattering of a plane wave from a rigid sphere, and the expression written in terms of sinc functions has been shown to be the most reliable solution in terms of accuracy.
