ENVIRONMENTAL RADIOACTIVITY IN GREENLAND IN 1980

A. Aarkrog, Henning Dahlgaard, Elis Holm*, Heinz Hansen,
J. Lippert and Karen Nilsson

* University of Lund, Sweden

Abstract. Measurements of fallout radioactivity in Greenland in 1980 are reported. Strontium-90 (and Cesium-137 in most cases) was determined in samples of precipitation, sea water, vegetation, animals, and drinking water. Estimates are given of the mean contents of ^{90}Sr and ^{137}Cs in the human diet in Greenland in 1980. Provisional results of the $^{239,240}\text{Pu}$ and ^{241}Am measurements on samples from the expedition to Thule in August 1979 and from the Swedish YMER expedition in 1980 are presented.

ABBREVIATIONS AND UNITS

J: joule: the unit of energy; $1 \text{ J} = 1 \text{ Nm} (= 0.239 \text{ cal})$
Gy: gray: the unit of absorbed dose = $1 \text{ J kg}^{-1} (= 100 \text{ rad})$
Sv: sievert: the unit of dose equivalent = $1 \text{ J kg}^{-1} (= 100 \text{ rem})$
Bq: becquerel: the unit of radioactivity = $1 \text{ s}^{-1} (= 27 \text{ pCi})$

cal: calorie = 4.186 J
rad: 0.01 Gy
rem: 0.01 Sv
Ci: curie: $3.7 \cdot 10^{10} \text{ Bq} (= 2.22 \cdot 10^{12} \text{ dpm})$

T: tera: 10^{12}
G: giga: 10^9
M: mega: 10^6
m: milli: 10^{-3}
 μ : mikro: 10^{-6}
n: nano: 10^{-9}
p: pico: 10^{-12}
f: femto: 10^{-15}
a: atto: 10^{-18}

cap: caput: (per individual)

TNT: trinitrotoluol; 1 Mt TNT: nuclear explosives equivalent to 10^9 kg TNT .

cpm: counts per minute
dpm: disintegrations per minute
OR: observed ratio
CF: concentration factor
FP: fission products
 μR : micro-roentgen, 10^{-6} roentgen
S.U.: pCi ^{90}Sr (g Ca) $^{-1}$
O.R.: observed ratio
M.U.: pCi ^{137}Cs (g K) $^{-1}$

V: vertebrae
m: male
f: female
nSr: natural (stable) Sr

eqv. mg KCl: equivalents mg KCl: activity as from 1 mg KCl
(~ 0.88 dpm)

S.D.: standard deviation: $\sqrt{\frac{\Sigma(\bar{x}-x_i)^2}{(n-1)}}$

S.E.: standard error: $\sqrt{\frac{\Sigma(\bar{x}-x_i)^2}{n(n-1)}}$

U.C.L.: upper control level

L.C.L.: lower control level

S.S.D.: sum of squares of deviation: $\Sigma(\bar{x}-x_i)^2$

f: degrees of freedom

s²: variance

v²: ratio between the variance in question and the residual variance

P: probability fractile of the distribution in question

n: coefficient of variation, relative standard deviation

ANOVA: analysis of variance

A: relative standard deviation 20-33%

B: relative standard deviation >33%, such results are not considered significantly different from zero activity

B.D.L.: below detection limit

In the significance test the following symbols were used:

* : probably significant (P > 95%)

** : significant (P > 99%)

***: highly significant (P > 99.9%)

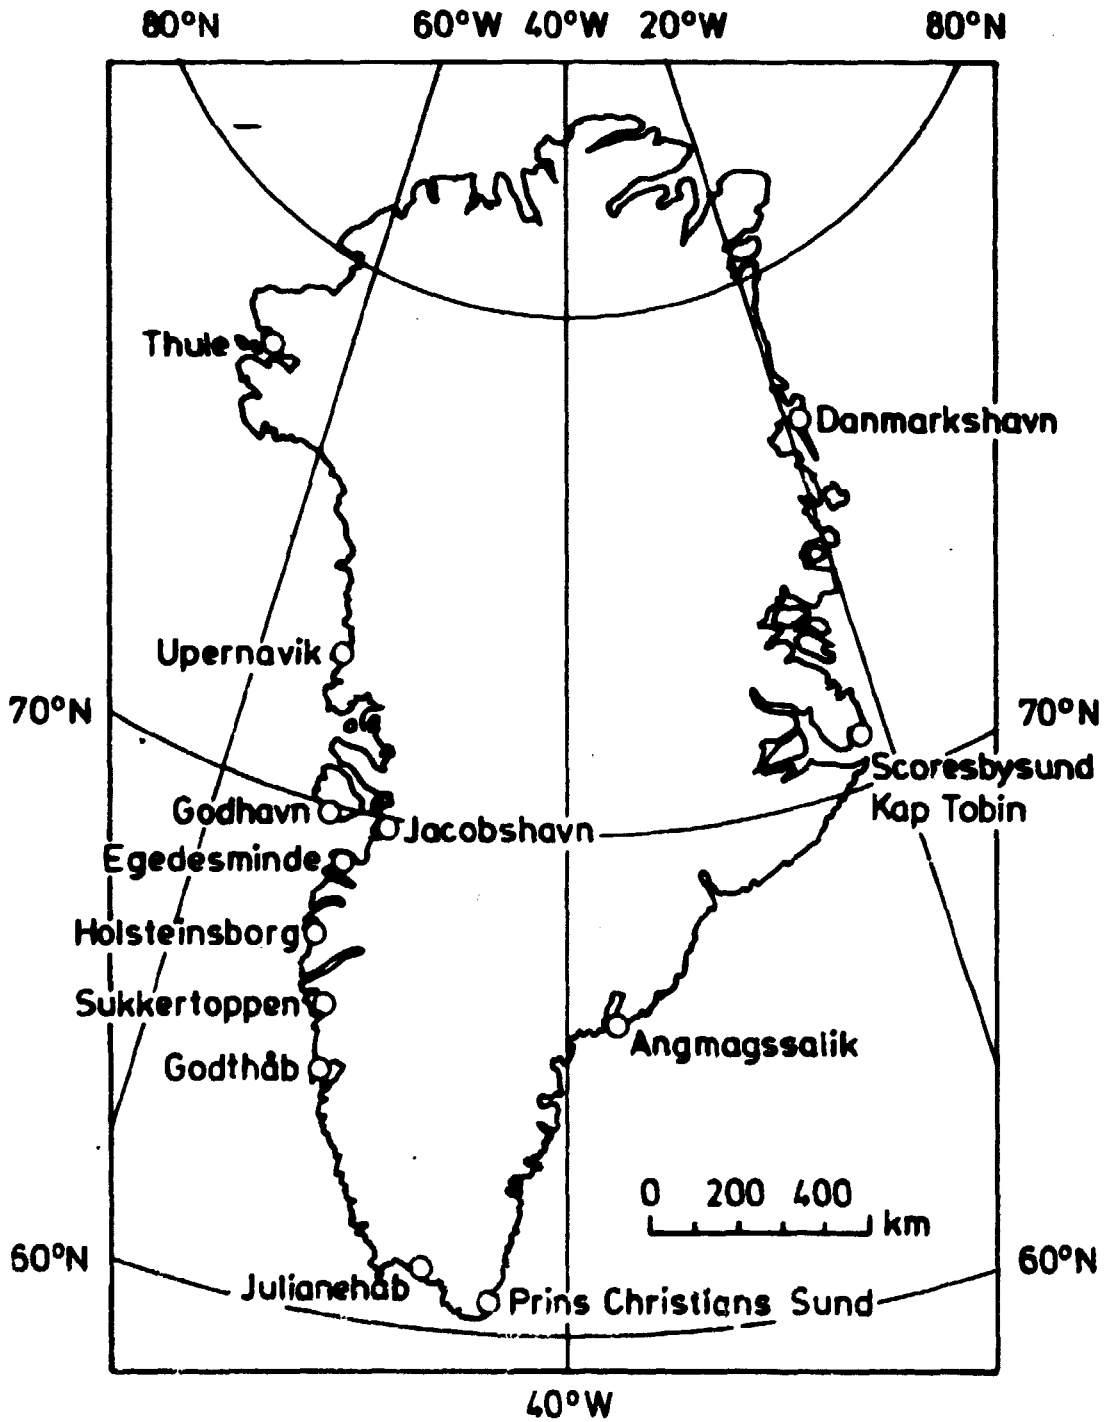

Fig. 1. Greenland.

1. INTRODUCTION

1.1.

In 1980 the sampling programme was similar to that used in previous years but for a few minor modifications.

1.2.

As hitherto, samples were collected through the local district physicians and the head of the telestations.

1.3.

The estimated mean diet in Greenland was the same as that in 1962, i.e., it agreed with the estimate given by Professor E. Hoff-Jørgensen, Ph.D.

1.4.

The environmental studies in Greenland were carried out together with corresponding investigations in Denmark (cf. Risø Report No. 447²) and in the Faroes (cf. Risø Report No. 448³).

1.5.

The present report does not repeat information concerning sample collection and analysis already given in ref. 1.

1.6.

In the appendices (A, B and C) we have as uncommented tables given provisional results of our investigations of transuranics (Pu and Am) and ¹³⁷Cs at Thule in August 1979. The expedition to Thule in 1979 was supported by the Commission of the European Communities with funds from its Radiation Protection programme. Furthermore, appendix D shows some provisional results from the Swedish YMER 1980 expedition. The samples were collected by Professor Bertil Persson and Dr. Elis Holm, Lund University.

2. RESULTS AND DISCUSSION

2.1. Strontium-90 in precipitation

Table 2.1.1 shows the results of the measurements.

Table 2.1.1. Strontium-90 in precipitation in Greenland in 1980

*Combined with Jan-March 1981.

The missing amount of precipitation was kindly supplied by Mr. Gunnar Nielsen, Danish Meteorological Institute. The annual amounts at the locations according to Danish Meteorological Institute are shown in bracket.

The ⁹⁰Sr levels in 1980 at the Greenland stations were 0.88 ± 0.51 (1 S.D.) times the 1979 figures. In Denmark²⁾ and the Faroes³⁾ the fallout levels decreased similarly from 1979 to 1980.

Fig. 2.1 shows the accumulated ⁹⁰Sr at the various stations in Greenland, since measurements began in 1962.

Fig. 2.1. Accumulated ⁹⁰Sr at Prins Chr. Sund, Godthåb, Godhavn, Kap Tobin and Upernavik calculated from precipitation measurements since 1952. The accumulated fallout by 1962 was estimated from the Danish data (cf. Rise Report No. 447²), Appendix D) and from the ratio between the ⁹⁰Sr fallout at the Greenland stations and the fallout in Denmark in the period 1962-1974.

2.2. Strontium-90 in sea water

Four samples of surface water were obtained in August 1979. Table 2.2.1 shows the results. The ⁹⁰Sr level was comparable with those of the previous years. The ¹³⁷Cs/⁹⁰Sr mean ratio was 1.2 (1 S.D.), i.e. there was no indication of any surplus ¹³⁷Cs in Greenland waters in the 1980 samples.

Tritium was measured in sea water from 1979 and 1980 (Table 2.2.2), the levels corresponded to those found in sea water col-

lected in Denmark of similar salinities (cf. Risø Report No. 447²), Tables 7.3.4 and 7.3.5).

The concentration in the East Greenland waters were as usual higher than the levels along the west coast of Greenland.

2.3. Strontium-90 and Cesium-137 in terrestrial animals

Six samples of lamb were received from SW-Greenland in 1980. The mean levels were 0.24 Bq ^{90}Sr kg^{-1} meat and 42 Bq ^{137}Cs kg^{-1} . The lamb bones contained 2600 Bq ^{90}Sr (kg Ca) $^{-1}$.

Table 2.3. Strontium-90 and Cesium-137 in terrestrial animals collected in Greenland in 1980

2.5. Strontium-90 and Cesium-137 in vegetation

Lichen, moss, grass and seaweed were collected at a few locations along the Greenland coast during the summer.

The ^{90}Sr and ^{137}Cs levels in lichen compared with those from previous years are shown in Fig. 2.5. As mentioned in Risø Report No. 405¹⁾ the decrease observed in 1978 was probably due to the lack of samples from the west coast that year.

The geometric mean levels in moss and lichen were 92 Bq ^{90}Sr kg^{-1} and 450 Bq ^{137}Cs kg^{-1} .

A fucus sample was obtained from Prins Chr. Sund in June. It contained 0.055 Bq ^{90}Sr kg^{-1} (wet) (36% dry matter) (73 Bq ^{90}Sr $(\text{kg Ca})^{-1}$) and 0.44 Bq ^{137}Cs kg^{-1} (42 Bq ^{137}Cs $(\text{kg K})^{-1}$).

Table 2.5.1. Strontium-90 and Cesium-137 in terrestrial vegetation samples collected in Greenland in 1980

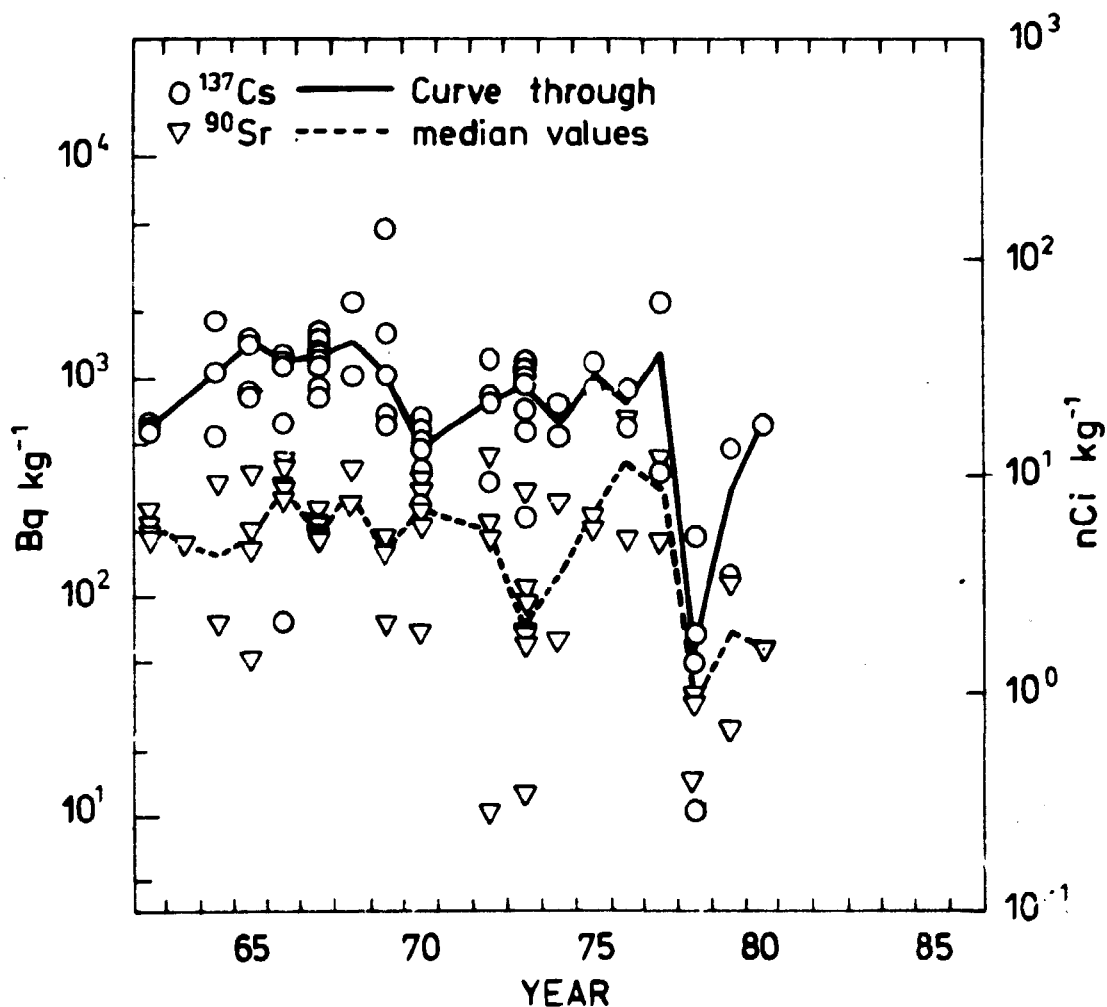

Fig. 2.5. Cesium-137 and Strontium-90 in lichen (fresh weight) collected along the Greenlandic coast, 1962-1980.

2.6. Strontium-90 in drinking water

Quarterly samples of drinking water were collected from a number of locations in Greenland. Table 2.6.1 shows the results from 1980, and Fig. 2.6 the geometric annual means of all samples for the period 1962-1980.

Table 2.6.1. Strontium-90 in drinking water collected in Greenland in 1979 and 1980. (Unit: Bq m⁻³)

Godthåb	17.1			
Upernavik	0.5 B	0.3 B		
Scoresbysund 1979			15.7	22

Fig. 2.6. Strontium-90 in Greenlandic drinking water (Geometric mean), 1962-1980.

As in previous years, we found it most expedient to choose the geometric mean of all figures, i.e. 19 Bq $^{90}\text{Sr m}^{-3}$ (0.53 pCi l^{-1}) as representative of the mean level of ^{90}Sr in Greenland drinking water in 1980, this level was not significantly different from that observed in recent years (Fig. 2.6). Some of the levels (e.g. those from Prins Chr. Sund) are surprisingly high as compared to present rain concentrations (cf. Table 2.1.1). We assume that evaporation from the drinking water reservoirs is responsible for the higher ^{90}Sr levels. Tritium measurements show (Table 2.6.2) that the drinking water at Prins Chr. Sund shows similar tritium levels as drinking water from other locations, hence evaporation seems to be a likely explanation. However, it is remarkable and not explainable at present, why Upernavik shows drinking water tritium concentrations just as high as those of the locations, despite the low ^{90}Sr levels in drinking water from Upernavik.

Table 2.6.2. Tritium in drinking water collected in Greenland in January-March 1980

Location	$\text{kBq } ^3\text{H m}^{-3}$ $\pm 1 \text{ S.E.}$
Danmarkshavn	7.6 ± 0.92
Scoresbysund	4.1
Prins Chr. Sund	2.6 ± 0.37
Godthåb	5.7 ± 0.18
Upernavik	5.7 ± 1.30

The error term is 1 S.E. of the mean of double determinations.

3. ESTIMATE OF THE MEAN CONTENTS OF ^{90}Sr AND ^{137}Cs IN THE HUMAN DIET IN GREENLAND IN 1980

3.1. The annual quantities

The estimate of the daily per capita intake of the different foods in Greenland is still based on the figures given in 1962 by Professor E. Hoff-Jørgensen, Ph.D., in Risø Report No. 65¹⁾.

3.2. Milk products

All milk consumed in Greenland was imported as milk powder from Denmark. The mean radioactivity content in milk prepared from Danish dried milk produced in 1980 was $0.127 \text{ Bq } ^{90}\text{Sr kg}^{-1}$ and $0.111 \text{ Bq } ^{137}\text{Cs kg}^{-1}$ 2).

Cheese was also imported from Denmark and contained $0.90 \text{ Bq } ^{90}\text{Sr kg}^{-1}$ and $0.080 \text{ Bq } ^{137}\text{Cs kg}^{-1}$.

3.3. Grain products

All grain was imported from Denmark. It is assumed that only grain from the harvest of 1979 was consumed in Greenland during 1980. The daily per capita consumption was: rye flour (100% extraction): 80 g, wheat flour (75% extraction): 110 g, rye flour (70% extraction): 20 g, biscuits (rye, 100% extraction): 27 g, and grits: 25 g. The content of ^{90}Sr in these five products was 0.74, 0.15, 0.15, 0.55 and 0.30 Bq kg^{-1} respectively. Hence the mean content of ^{90}Sr in grain products was 0.39 Bq kg^{-1} . The content of ^{137}Cs in the five products was 0.45, 0.14, 0.23, 0.34 and 0.16 Bq kg^{-1} . Hence the mean content of ^{137}Cs in grain products was 0.26 Bq kg^{-1} .

The activity levels in rye flour (100% extraction), wheat flour (75% extraction), and grits were all taken from Tables 5.9.1 and 5.9.2 in Risø Report No. 447²⁾. The ^{90}Sr level in rye flour

(70% extraction) was calculated analogously with the level in wheat flour (75% extraction), i.e. as one-fifth of the whole-grain activity. The ^{137}Cs content in rye flour (70% extraction) was calculated as one half of the whole-grain level in rye in analogy with the ratio between ^{137}Cs in whole wheat grain and in wheat flour (75% extraction)²⁾. The ^{90}Sr and ^{137}Cs contents in biscuits were calculated by dividing the levels of the rye flour (100% extraction) by 1.35, since 1 kg flour yields 1.35 kg bread²⁾.

3.4. Potatoes, other vegetables, and fruit

The Danish mean levels for 1980 were used²⁾ since the local production is insignificant compared with imports from Denmark.

The Danish mean levels were: in potatoes 0.083 Bq ^{90}Sr kg⁻¹ and 0.077 Bq ^{137}Cs kg⁻¹, in other vegetables 0.34 Bq ^{90}Sr kg⁻¹ and 0.084 Bq ^{137}Cs kg⁻¹, and in fruit 0.05 Bq ^{90}Sr kg⁻¹ and 0.03 Bq ^{137}Cs kg⁻¹.

3.5. Meat

Nearly all meat consumed in Greenland is assumed to be of local origin. Approx. 10% comes from sheep, 5% from reindeer, 60% from seals, 5% from whales, and 20% from sea birds and eggs.

The activity in lamb was estimated from 2.3. Activity in seals was estimated from 2.4. The levels of whales, sea birds and eggs were taken from the 1978 analyses¹⁾ and reindeer from 1979. Hence the mean levels in Greenland meat from 1980 were 0.031 Bq ^{90}Sr kg⁻¹ and 5.8 Bq ^{137}Cs kg⁻¹.

$$(^{90}\text{Sr}: 0.1 \times 0.24 + 0.05 \times 0.072 + 0.6 \times 0.0025 + 0.05 \times 0.0013 \\ + 0.2 \times 0.0070 = 0.031 \text{ Bq kg}^{-1})$$

$$(^{137}\text{Cs}: 0.1 \times 42 + 0.05 \times 24 + 0.6 \times 0.43 + 0.05 \times 0.70 + 0.2 \times 0.35 \\ = 5.8 \text{ Bq kg}^{-1})$$

3.6. Fish

All fish consumed was of local origin, and the mean levels from 2.4 were used, i.e. 0.0056 Bq ^{90}Sr kg^{-1} and 0.30 Bq ^{137}Cs kg^{-1} .

3.7. Coffee and tea

The Danish figures for 1980²⁾ were used for coffee and tea, i.e. 0.66 Bq ^{90}Sr kg^{-1} and 2.21 Bq ^{137}Cs kg^{-1} .

3.8. Drinking water

The geometric mean calculated in 2.6 was used as the mean level of ^{90}Sr in drinking water, i.e. 19 Bq ^{90}Sr m^{-3} . The ^{137}Cs content was as previously¹⁾ estimated at 1/4 of the ^{90}Sr content, i.e. approx. 5 Bq ^{137}Cs m^{-3} .

Tables 3.1 and 3.2 show the diet estimates of ^{90}Sr and ^{137}Cs respectively.

Table 3.1. Estimate of the mean content of ^{90}Sr in the human diet in Greenland in 1980

Type of food	Annual quantity in kg	Bq ^{90}Sr per kg	Total Bq ^{90}Sr	Percentage of total Bq ^{90}Sr in food
Milk and cream	78	0.127	9.91	13.8

The mean annual calcium intake is estimated to be 0.56 kg (approx. 0.2-0.25 kg creta praeparata). Hence the $^{90}\text{Sr}/\text{Ca}$ ratio in Greenland total diet in 1980 was 129 Bq ^{90}Sr $(\text{kg Ca})^{-1}$ or 3.5 pCi ^{90}Sr $(\text{g Ca})^{-1}$ and the daily intake was 0.20 Bq ^{90}Sr or 5.3 pCi ^{90}Sr .

Table 3.2. Estimate of the mean content of ^{137}Cs in the human diet in Greenland in 1980

Type of food	Annual quantity in kg	Bq ^{137}Cs per kg	Total Bq ^{137}Cs	Percentage of total Bq ^{137}Cs in food
Milk and cream	78	0.111	8.66	2.4
Cheese	2.5	0.080	0.20	0.1
Grain products	95.6	0.26	24.86	6.9
Potatoes	32.8	0.077	2.52	0.7
Vegetables	5.5	0.084	0.46	0.1
Fruit	13.5	0.03	0.41	0.1
Meat and eggs	45.6	5.8	264.48	73.7
Fish	127.6	0.30	38.28	10.7
Coffee and tea	7.3	2.21	16.13	4.5
Drinking water	548	0.005	2.74	0.8
Total			358.74	

The mean annual potassium intake is estimated to be approx. 1.2 kg. Hence the $^{137}\text{Cs}/\text{K}$ ratio becomes 300 Bq ^{137}Cs (kg K) $^{-1}$ or 8.1 pCi ^{137}Cs (g K) $^{-1}$. The daily intake in 1980 from food was 0.98 Bq ^{137}Cs or 26.5 pCi ^{137}Cs .

3.9. Discussion

The most important ^{90}Sr source in the Greenland diet is still grain products, which contribute 52% of the total ^{90}Sr content in the diet. Milk products came next in importance, contributing 17%. Approx. 80% of the ^{90}Sr in the food consumed in Greenland in 1980 originated from imported Danish food.

Meat is still the most important ^{137}Cs source in the Greenland diet, contributing 74% of the total content in 1980. Approx. 85% of the ^{137}Cs in the Greenland diet in 1980 came from local products.

As compared with the 1979 figures, the ^{90}Sr contents in the total diet in 1980 was 14% lower than the 1979 level.

The ^{137}Cs level was 80% of the level found in 1979. As earlier discussed¹⁾ the great variations from year to year are primarily due to the variations in the ^{137}Cs levels in the meat samples obtained.

Fig. 3.1. Strontium-90 in Greenlandic diet, 1962-1980.

Fig. 3.2. Cesium-137 in Greenlandic diet, 1962-1980.

To estimate the maximum per capita intakes of ^{90}Sr and ^{137}Cs in Greenland in 1980 we assume¹⁾ that the only grain product consumed by a person is dark rye bread, and that he only eats lamb meat. His daily intake of ^{90}Sr is thus 0.31 Bq (205 Bq ^{90}Sr (kg Ca)⁻¹) and his ^{137}Cs intake 5.6 Bq day⁻¹ (using the quantities in Tables 3.1 and 3.2). At the lower limit we can imagine a person eating white bread and seal and drinking water with hardly any activity (e.g. water formed by the melting of old ice). In this case the daily intakes are 0.13 Bq ^{90}Sr (85 Bq ^{90}Sr (kg Ca)⁻¹) and 0.28 Bq ^{137}Cs . Hence the ratios between the levels in the maximum and minimum diets become 2 for ^{90}Sr and 20 for ^{137}Cs .

The ^{90}Sr content of the Greenland diet in 1980 was 82% of the estimated Danish mean content²⁾, and 63% of the Faroese level³⁾. The ^{137}Cs level in the total diet in Greenland was 2.5 times that of the Danish diet and 20% of the Faroese diet level.

4. CONCLUSION

4.1.

The ^{90}Sr fallout rates in 1980 were the following: Godthåb: $4.7 \text{ Bq } ^{90}\text{Sr m}^{-2}$; Prins Chr. Sund: approx. $7.1 \text{ Bq } ^{90}\text{Sr m}^{-2}$; Upernavik: $3.7 \text{ Bq } ^{90}\text{Sr m}^{-2}$. The accumulated fallout levels by the end of 1980 were estimated at approx. $1050 \text{ Bq } ^{90}\text{Sr m}^{-2}$ at Godhavn, $1300 \text{ Bq } ^{90}\text{Sr m}^{-2}$ at Godthåb, $4600 \text{ Bq } ^{90}\text{Sr m}^{-2}$ at Prins Chr. Sund, and $460 \text{ Bq } ^{90}\text{Sr m}^{-2}$ at Upernavik.

4.2.

The food consumed in Greenland in 1980 contained on the average $129 \text{ Bq } ^{90}\text{Sr (kg Ca)}^{-1}$, and the daily mean intake of ^{137}Cs was estimated at 0.98 Bq . The most important ^{90}Sr contributors to the diet were grain products and milk products, together accounting for approx. 65% of the total ^{90}Sr content of the diet. Cesium-137 originated mainly from meat (reindeer and lamb) and fish, contributing approx. 85% of the total ^{137}Cs content of the diet.

4.3.

No ^{90}Sr analyses of human bone samples have hitherto been carried out on the population of Greenland. Considering the estimated ^{90}Sr levels in the diet, it seems probable⁴⁾, however, that the 1980 ^{90}Sr levels of humans in Greenland were on the average rather similar to those found in Denmark, i.e. the mean levels in human bone in Greenland were approx. $30 \text{ Bq } ^{90}\text{Sr (kg Ca)}^{-1}$ (vertebrae). From diet measurements the ^{137}Cs content in Greenlanders was estimated at $900 \text{ Bq } ^{137}\text{Cs (kg K)}^{-1}$.

ACKNOWLEDGEMENTS

The authors wish to thank Miss Annaholm Petersen, Mrs. Else Marie Sørensen, Mrs. Anna Madsen, and Mrs. Jytte Clausen for their conscientious performance of the analyses.

Our thanks are furthermore due to the district physicians, the telestations, GTO, and all other persons and institutions in Greenland and Denmark who have contributed by collecting samples.

APPENDIX A

Thule sediments and sea water

Tables A.1-A.18 contain the provisional results of the plutonium, americium and ^{137}Cs analysis of Thule sediments collected in August 1979. Most of these data were presented in the 1979 report (Rise-R-423). However, the measurements performed at the locations V, X, Y which are those within 1 km from the point of impact have not been published earlier. Furthermore, all tables contain the Pu-levels in Bq (shown in brackets). Tables A.19 and A.20 show the results of the sea water analyses.

APPENDIX B

Biological samples from Thule

Tables B.1-B.18 show the provisional results of the plutonium and americium analysis on benthic animals collected at Thule in August 1979. Table B.19 presents the data on sea plants and Table B.20-B.23 show analysis of fish, sea birds, marine mammals and terrestrial samples respectively.

APPENDIX C

Biomass in Thule sediments

During the Thule expedition in August 1979 the biomass of benthic organisms were determined at 10 locations. The mean depth of the 10 locations was 167 ± 52 (1 S.D.) m.

Table C.1. Biomass (soft tissue) of benthos determined at Thule, August 1979 at locations B, C, D, K, H, G, P, I, X, Y (0.1 m^2 sampled by van Veen sampler at each of the ten locations)

Species	Number per $\text{m}^2 \pm 1 \text{ S.E.}$	Fresh weight in g m^{-2} $\pm 1 \text{ S.E.}$	% of total weight

Total		256.4	

APPENDIX D

Preliminary results from the Swedish YMER 1980 expedition

In June-September 1980 Professor Bertil Persson and Dr. Elis Holm, Lund University, participated in the Swedish scientific YMER expedition to Spitzbergen and NE-Greenland. A number of samples collected at this expedition have been analysed by Risø as a part of the current cooperation between Lund University and Risø. The provisional results are presented in Tables D.1 (sea water) and D.2 (biota). The data will form part of the EEC-funded radioecological studies of the North Atlantic Region (BIO/B-339-DK(G)).
