Swarm, a three-satellite constellation to study the dynamics of the Earth's magnetic field and its interactions with the Earth system, is expected to be launched in late 2013. The objective of the *Swarm* mission is to provide the best ever survey of the geomagnetic field and its temporal evolution, in order to gain new insights into the Earth system by improving our understanding of the Earth's interior and environment. In order to derive advanced models of the geomagnetic field (and other higher-level data products) it is necessary to take explicit advantage of the constellation aspect of *Swarm*. The *Swarm* SCARF (*Satellite Constellation Application and Research Facility*) has been established with the goal of deriving Level-2 products by combination of data from the three satellites, and of the various instruments. The present paper describes the *Swarm* input data products (Level-1b and auxiliary data) used by SCARF, the various processing chains of SCARF, and the Level-2 output data products determined by SCARF.

Key words: Earth's magnetic field, core field, lithosphere, ionosphere, magnetosphere, electromagnetic induction, comprehensive inversion, *Swarm* satellites.

1. Introduction

Swarm, a constellation mission comprising three identical satellites to study the dynamics of the Earth's magnetic field and its interactions with the Earth system (Friis-Christensen *et al.*, 2006, 2008) is expected to be launched in late 2013. The objective of the *Swarm* mission is to provide the best ever survey of the geomagnetic field and its temporal evolution, in order to gain new insights into the Earth system by improving our understanding of the Earth's interior and environment.

Each of the three *Swarm* satellites will make high-precision and high-resolution measurements of the strength, direction and variation of the magnetic field, complemented

by precise navigation, accelerometer, plasma and electric field measurements. These observations will be provided as Level-1b data, which are the calibrated and formatted time series of e.g. the magnetic field measurements taken by each of the three *Swarm* satellites. These Level-1b data, as well as the higher-Level *Swarm* data products described in this paper, will be distributed by ESRIN (Frascati/I).

Swarm will simultaneously obtain a space-time characterisation of both the internal field sources in the Earth and the ionospheric-magnetospheric current systems. The research objectives assigned to the mission are: (a) studies of core dynamics, geodynamo processes, and core-mantle interaction; (b) mapping of the lithospheric magnetisation and its geological interpretation; (c) determination of the 3-D electrical conductivity of the mantle; and (d) investigation of electric currents flowing in the magnetosphere and ionosphere.

A challenging part, however, is the separation of the var-

ious sources (in the core, lithosphere, ionosphere, magnetosphere etc.) which in total yields the measured magnetic field. A constellation consisting of several satellites, like *Swarm*, opens new possibilities for exploring the geomagnetic field from space beyond those achievable with single-satellites. At first glance one would expect that using simultaneous data from N satellites results in a reduction of the error of geomagnetic field models by \sqrt{N} , since the amount of data is increased by N compared to one single satellite. This error reduction by \sqrt{N} of course only holds if the data are statistically independent, which is highly idealistic and unrealistic since the main limiting factor for improved field modelling is not the measurement error but the dynamic behaviour of external sources. Treating data from a constellation of N satellites in a “single-satellite” approach thus typically results in an improvement of the model error by less than \sqrt{N} . However, if *explicit* advantage is taken of the constellation, there is some potential for model improvement better than \sqrt{N} . A constellation of three satellites can do more than three single satellites, and therefore a (smart) combination of data from all three satellites, and of the various instruments, allows for taking full advantage of the *Swarm* constellation. Analysis of the *Swarm* data will greatly improve existing and provide new models of the near-Earth magnetic field of high resolution and authenticity compared to what is possible with single-satellite missions like Ørsted (Olsen, 2007) and CHAMP (Reigber *et al.*, 2005).

In recognition of the large effort needed to extract the various types of scientific information from the complex set of observations a group of institutions and organisations have joined the *SMART* consortium (*Swarm Magnetic and Atmospheric Research Team*). The purpose of the consortium is to contribute to the optimal science return from the *Swarm* mission by a coordinated effort to exploit the constellation aspects of this unique mission. This effort is obviously in accordance with ESA’s aim of providing the scientific community with the best possible products from the *Swarm* mission, and it was decided to establish a *Swarm SCARF (Satellite Constellation Application and Research Facility)*, with the purpose of deriving commonly used scientific models and quantities, the so-called Level-2 products and make them available to the scientific community at large. Advanced *Swarm*-derived models of the geomagnetic field and other Level-2 data products are determined from the Level-1b data and auxiliary (i.e. non-*Swarm*) data and provide the prospect of investigating hitherto undetected features of the Earth’s interior.

SCARF (sometimes also called “Level-2 Processing System”, *L2PS*) comprises in its present form a joint effort between the six European partners: DTU (Lyngby/DK), TU Delft (Delft/NL), BGS (Edinburgh/GB), ETH (Zürich/CH), GFZ (Potsdam/D) and IPGP (Paris/F) with contributions from CUP (Prague/CZ), NOAA (Boulder/USA) and GSFC/NASA (Greenbelt/USA). The team behind *SCARF* has designed and implemented algorithms to derive advanced models of the geomagnetic field describing sources in the core, lithosphere, ionosphere and magnetosphere, models of the electrical conductivity of Earth’s mantle and time series of thermospheric wind and density at

the positions of the *Swarm* satellites. These models, which are state-of-the-art implementations of current knowledge, are intended to facilitate and increase the use of the *Swarm* data by a much wider community than the one represented in the *SMART* consortium itself.

The work performed by *SCARF* is a major extension on the “End-To-End” mission simulation that has been performed during Phase A of the *Swarm* mission, the results of which have been published in a special issue (Vol. 58 No. 4, 2006) of *Earth, Planets and Space* (cf. Olsen *et al.*, 2006 for an overview).

The present paper describes the *Swarm* input data products (Level-1b and auxiliary data) used by *SCARF*, the various processing chains of *SCARF*, and the Level-2 output data products determined by *SCARF* and distributed by ESA through the PDGS (Payload Data Ground Segment) at ESRIN.

The content of the paper is as follows: Section 2 summarizes the various Level-1b data, with emphasis on the 1 Hz time series of the magnetic field observations. Section 3 describes the various processing chains and resulting Level-2 data products. All processing chains have been tested using synthetic data from a full mission simulation; the creation of this synthetic data set is described in Section 4. Data processing time-line and data availability are discussed in Section 5.

2. Swarm Level-1b Products

The Level-1b products of the *Swarm* mission contain time-series of quality-screened, calibrated, and corrected measurements given in physical, SI units in geo-localized reference frames. Level-1b products are provided individually for each of the three satellites *Swarm A*, *Swarm B*, and *Swarm C* on a daily basis, i.e. each product contains all available data of that day from 00:00 until (but not including) 24:00 UT time. An example illustrating the file-naming convention of *Swarm* Level-1b 1 Hz magnetic product *MAGx_LR* from 23. February 2013 is given in Fig. 1.

Table 1 lists the various Level-1b data products. *Ephemeris Products* are data obtained by the GPS receiver, the accelerometer and the star tracker; the *Magnetic Products* contain measurements taken by the two magnetometers (augmented with position and attitude measured by the star tracker), while the *Plasma Products* contain data obtained by the Thermal Ion Imager and the Langmuir probe. Most Level-1b products are provided in the Common Data Format (CDF, see Goucher and Mathews (1994) and <http://cdf.gsfc.nasa.gov/>) which is a file format optimized for storing time series, although data from the GPS receiver are provided in the RINEX and SP3 formats as is typical for these kind of data.

Probably the most important Level-1b product, *MAGx_LR* (where “x” is a placeholder for “A”, “B”, or “C” indicating the satellite), contains 1 Hz time series with magnetic field observations from each of the three satellites. The content of the product is described in more detail in Table 2. In addition to time and position it contains the magnetic scalar intensity F and the three components of the magnetic vector $\mathbf{B}_{\text{NEC}} = (B_N, B_E, B_C)$ in the North-East-Center (NEC) local Cartesian coordinate frame (where B_N is the component

Fig. 1. Example illustrating the filename of the *Swarm*-A Level-1b low-rate magnetic product MAGx_LR from 23. February 2013.

Table 1. *Swarm* Level-1b products. The “x” in the product name is a placeholder for “A”, “B”, or “C” indicating the satellite.

Ephemeris Products

Type	Descriptive Name	Format	Contents
GPSx_RO	RINEX Observations	RINEX 3.0	Processed and corrected data from the GPS receiver, 0.1 Hz sampling
GPSx_RN	RINEX Navigation data	RINEX 3.0	GPS navigation data from the GPS receiver
GPSx_NAV	Navigational Solution	SP3	Position and velocity from on-board GPS receiver navigational solution, 1 Hz sampling
MODx_SC	Medium-Precision Orbit Determination	SP3	Position and velocity from automated, medium-precision orbit determination based on GPSx_RO data, 1 Hz sampling
STRx_ATT	Attitude	CDF	Processed and corrected attitude information of the spacecraft frame, from the Star Tracker, 1 Hz sampling
ACCx_PR	Non-gravitational Accelerations	CDF	Pre-processed linear and angular, non-gravitational acceleration measurements from the accelerometer (Fully calibrated and corrected linear, non-gravitational accelerations are provided as Level-2 product ACCxPOD.2-), 1 Hz sampling

Magnetic Products

Type	Descriptive Name	Format	Contents
MAGx_LR	Low Rate (1 Hz) magnetic data	CDF	Calibrated and corrected magnetic vector and scalar measurements, interpolated to UTC seconds and provided in VFM sensor as well as in NEC frame
MAGx_HR	High Rate (50 Hz) magnetic data	CDF	Calibrated and corrected magnetic vector measurements, provided in VFM sensor as well as in NEC frame
MAGx_CA	Magnetic calibration data	CDF	Magnetic scalar calibration data for long-term VFM analysis

Plasma Products

Type	Descriptive Name	Format	Contents
EFIx_PL	Plasma data	CDF	Processed and corrected plasma measurements from the EFI instruments including electric field vector, plasma density, plasma electron and ion temperatures, 2 Hz sampling
LPx_CA	Langmuir probe calibration data	CDF	Offset determination mode data and corresponding estimated calibration parameters
TIIx_CA	Thermal Ion Imager calibration data	CDF	Daily calibration parameters used for monitoring and optimisation of the TII instrument performance

towards geographic North, B_E is the component towards geographic East, and B_C is the component towards the center of the Earth). In addition, the magnetic vector \mathbf{B}_{VFM} in the instrument frame of the Vector Field Magnetometer (VFM) is given, where

$$\mathbf{B}_{NEC} = \underline{\underline{R}}_q \underline{\underline{R}}_3 \mathbf{B}_{VFM} \quad (1)$$

with

$$\underline{\underline{R}}_3 = \begin{pmatrix} \cos \gamma & -\sin \gamma & 0 \\ \sin \gamma & \cos \gamma & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} \cos \beta & 0 & \sin \beta \\ 0 & 1 & 0 \\ -\sin \beta & 0 & \cos \beta \end{pmatrix} \times \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos \alpha & -\sin \alpha \\ 0 & \sin \alpha & \cos \alpha \end{pmatrix} \quad (2)$$

Table 2. Content of *Swarm* Level-1b Product MAGx_LR.

Element	Contents	Units
Timestamp	Time of observation	CDF_EPOCH
SyncStatus	Time reference information	—
Latitude	Latitude of observation in the <i>International Terrestrial Reference Frame</i> (ITRF)	degree
Longitude	Longitude of observation in the ITRF	degree
Radius	Radius of observation in ITRF	m
F	Magnetic field intensity	nT
dF_AOCS	Magnetic stray field correction intensity related to attitude control magneto-torquers	nT
dF_other	Magnetic stray field correction intensity of all other sources	nT
F_error	Error estimate on magnetic field intensity	nT
B_VFM	Magnetic field vector in the instrument frame of the VFM magnetometer	nT
B_NEC	Magnetic field vector in the NEC (North, East, Center) frame	nT
dB_AOCS	Magnetic stray field correction vector related to attitude control magneto-torquers (in VFM frame)	nT
dB_other	Magnetic stray field correction vector of all other sources (in VFM frame)	nT
B_error	Error estimates on magnetic field vector \mathbf{B}_{VFM} (in VFM frame)	nT
q_NEC_CRF	Rotation from NEC frame to STR Common Reference Frame (CRF), quaternion (NEC \leftarrow CRF)	—
Att_error	Error estimate on attitude information	degree/10 ³
Flags_F	Flags characterizing the magnetic field intensity measurement: spikes or gap in data, discrepancy between ASM and VFM, etc.	—
Flags_B	Flags characterizing the magnetic field vector measurement \mathbf{B}_{VFM} and \mathbf{B}_{NEC} : spikes or gap in data, discrepancy between ASM and VFM, etc.	—
Flags_q	Flags characterizing the attitude information: identification of active heads, blinding, etc.	—
Flags_Platform	Flags characterizing the spacecraft platform information: thruster activation, lack of telemetry, etc.	—
ASM_Freq_Dev	ASM reference frequency calibration data deviation for ASM stability assessment	Hz ^{1/2}

as the matrix describing the rotation of the magnetic field from the VFM system to the **Common Reference Frame** (CRF) of the star tracker (α , β and γ are the Euler angles describing this rotation; they are provided in the Level-2 data product MSW_EUL_2_) and

$$\underline{\underline{R}}_q = \begin{bmatrix} 1 - 2q_2^2 - 2q_3^2 & 2(q_1q_2 + q_3q_4) & 2(q_1q_3 - q_2q_4) \\ 2(q_1q_2 - q_3q_4) & 1 - 2q_1^2 - 2q_3^2 & 2(q_2q_3 + q_1q_4) \\ 2(q_1q_3 + q_2q_4) & 2(q_1q_4 - q_2q_3) & 1 - 2q_1^2 - 2q_2^2 \end{bmatrix} \quad (3)$$

as the rotation matrix from the CRF to the NEC coordinate frame, described by the quaternions $\mathbf{q}_{NEC \leftarrow CRF} = [q_1 \ q_2 \ q_3 \ q_4]^T$. Finally, the magnetic field corrections (dF_AOCS, dF_other, dB_AOCS, dB_other) that have been applied to the data, error estimates (F_error, B_error, Att_error) and flags characterizing the status of the various instruments and the spacecraft are also provided.

The quality of Level-1b magnetic and plasma products MAGx_LR and EFIX_PL can be inspected using quick-look products, essentially comprising various daily and mission-to-date plots designed to reveal a range of possible measurement problems (Beggan *et al.*, 2013).

The positions provided in the Level-1b data are generated automatically as part of the Level-1b processing as “Medium Precise Orbits” (MOD) with an expected accuracy not exceeding a few meters. In case higher precision of the position is needed (or for periods where the MOD automatic calculation yields less optimal results) it is recommended to use the positions provided by the “Precise Orbit Determination” (POD) chain (Level-2 product

SP3xCOM_2_) discussed in Section 3.2.

3. Swarm Level-2 Data Processing and Products

Depending on the complexity of the processing, there are two types of Level-2 products, which are called Cat-1 and Cat-2 products, respectively. Cat-1 data processing involves complex algorithms to derive Level-2 products describing specific sources of the Earth’s magnetic field like the lithospheric field or time series of the large-scale magnetospheric signal. Cat-1 products are derived by SCARF since scientific expertise is required during processing. In contrast, processing of Cat-2 products is less demanding, and therefore these products are derived by ESA on a daily basis in ESA’s *Swarm* PDGS using algorithms designed by SCARF. The processing runs automatically, leading to product release with minimum delay; Cat-2 products are tested for their near real time capability with processing delays of less than 1 hour. Cat-2 products are therefore suitable e.g. for space weather applications (Stolle *et al.*, 2013).

Table 3 gives an overview of Level-2 products, and Fig. 2 shows a generic processing flow chart of a typical Level-2 chain of SCARF. Input Level-1b data (shown in green) and auxiliary data (yellow) are used in the various processing blocks (orange) to produce Level-2 products (magenta). In a final step all Level-2 products are validated by inter-product comparison as well as comparison with independent data; details of this validation process are given in Beggan *et al.* (2013).

3.1 Level-2 products related to main magnetic sources

Figure 3 shows the various chains of SCARF that result in Level-2 magnetic products. Most of the chains use 1-Hz

Table 3. The *Swarm* Level-2 products.

Science Objective	Name	Format	Description
(needed for Level-1b processing)	MSW_EUL_2_	ASCII	Time series of Euler angles describing transformation from STR-CRF to VFM frame for all three <i>Swarm</i> satellites (3×3 Euler angles)
Core field	MCO_SHA_2_	ASCII	Spherical harmonic model of the core field and its temporal variation
Lithospheric field	MLI_SHA_2_	ASCII	Spherical harmonic model of the lithospheric field
Electrical conductivity of the mantle	MIN_1DM_2_	ASCII	1D model of mantle conductivity
	MIN_3DM_2_	ASCII	3D model of mantle conductivity
	MCR_1DM_2_	ASCII	1D <i>C</i> -responses
	MCR_3DM_2_	ASCII	3D <i>C</i> -response maps
External current systems	MMA_SHA_2_	CDF	Spherical harmonic model of the large-scale magnetospheric field and its Earth-induced counterpart
	MIO_SHA_2_	ASCII	Spherical harmonic model of the daily geomagnetic variation at middle latitudes (Sq) and low latitudes (EEJ)
Precise Orbit Determination (POD)	SP3xCOM_2_	SP3	Time series of position and velocity of the center of mass for satellite <i>x</i> (<i>x</i> = A, B or C)
	ACCxCAL_2_	CDF	Accelerometer calibration parameters for satellite <i>x</i>
	ACCxPOD_2_	CDF	Time series of non-gravitational accelerations estimated for satellite <i>x</i>
Magnetic Forcing of the Upper Atmosphere	ACCxAE_2_	CDF	Time series of calibrated and pre-processed accelerometer observations and of aerodynamic accelerations for satellite <i>x</i>
	DNSxWND_2_	CDF	Time series of neutral thermospheric density and wind speed for satellite <i>x</i>
Earth environment and Space-Weather (Cat-2 products)	IBIxTMS_2F	CDF	Ionospheric bubble index for satellite <i>x</i>
	TECxTMS_2F	CDF	Time series of the ionospheric total electron content for satellite <i>x</i>
	FAC_TMS_2F	CDF	Time series of field-aligned currents determined from combination of <i>Swarm</i> A and <i>Swarm</i> B
	FACxTMS_2F	CDF	Time series of field-aligned currents (single-satellite solution) for satellite <i>x</i>
	EEFxTMS_2F	CDF	Equatorial Electric Field for satellite <i>x</i>

magnetic field data from each of the three *Swarm* satellites (Level-1b product $MAGx_LR$) as input (exceptions are the chains that derive models of the electrical conductivity of the Earth's mantle which rely on time series of magnetospheric and induced fields as provided as Level-2 data). Models of the core, lithospheric, non-polar ionospheric and large-scale magnetospheric fields are derived using two independent chain branches: in the Comprehensive Inversion (CI) chain these sources are co-estimated in one huge inversion process; details are given in Sabaka *et al.* (2013). In the Dedicated Inversion (DI) chains the various sources are determined in a sequential approach after removing models describing the other sources; there are dedicated chains for the core field (Rother *et al.*, 2013), for the lithospheric field (Thébault *et al.*, 2013), for deriving the daily ionospheric variation at non-polar latitudes (Chulliat *et al.*, 2013) and for determining time-series of the large-scale magnetospheric contributions (Hamilton, 2013).

Processing of *Swarm* Level-1b products in order to derive Level-2 products requires auxiliary data and models, in particular indices describing the state of the Earth's environment. These auxiliary data (shown in yellow in Figs. 3 to 5) are: the 3-hour *Kp* index describing global geomagnetic activity (auxiliary data product $AUX_KP_2_$), hourly values of the *Dst*-index monitoring the strength of the magnetospheric ring-current ($AUX_DST_2_$), daily $F_{10.7}$ values of solar radio flux ($AUX_F10_2_$) and parameters of the Interplanetary Magnetic Field ($AUX_IMF_2_$). In addition, checked and corrected hourly mean values from the global network of ground magnetic observatories are provided as auxiliary data product $AUX_OBS_2_$; details of the data checking procedure are given in Macmillan and Olsen

(2013). Auxiliary data are used in the selection of *Swarm* data for deriving Level-2 products. In addition, the Comprehensive Inversion chain and the Dedicated Ionospheric chain also use magnetic observatory data in combination with the *Swarm* magnetic observations. Finally, observatory hourly means are also used in the validation of the magnetic Level-2 products (Beggan *et al.*, 2013).

In addition to auxiliary *data*, the processing also requires auxiliary *models* like the IGRF ($AUX_IGR_2_$) or more advanced models of the core field ($AUX_COR_2_$) and the lithospheric field ($AUX_LIT_2_$). Models of the electrical conductivity of the Earth's mantle ($AUX_MCM_2_$) and of the surface conductance of oceans and sediments ($AUX_OCM_2_$) are used to account for secondary, Earth-induced contributions connected to the temporal variations of magnetospheric and ionospheric origin. Finally, a model of the magnetic signature of ocean tides ($AUX_MTI_2_$) is provided.

In the following we briefly discuss the various Level-2 products.

Spherical Harmonic Models of the core, lithospheric, ionospheric and magnetospheric field. Models of the **core field and its time changes** are provided as spherical harmonic expansion coefficients in the Level-2 product $MCO_SHA_2_$ (where “M” indicates that the product describes a Magnetic source, “CO” stands for COre field, “SHA” denotes that the model is given as an expansion of a Spherical Harmonic Analysis, and “2” refers to the fact that this is a Level-2 data product. The last character, in this example “_”, indicates the generic form of the Level-2 product; other values are “C” if the product is derived in the Comprehensive Inversion chain or “D” if the product is

Fig. 2. Data flow in a typical Level-2 processing chain.

Fig. 3. Level-2 processing chains which result in magnetic Level-2 products.

derived in one of the **Dedicated Inversion** chains.)

The magnetic field vector, $\mathbf{B}_{\text{NEC}} = -\nabla V$, is described using a magnetic scalar potential V which is expanded into series of spherical harmonics. For the potential describing internal sources (in the core and lithosphere) this expansion reads

$$V = a \sum_{n=N_{\min}}^{N_{\max}} \sum_{m=0}^n (g_n^m \cos m\phi + h_n^m \sin m\phi) \times \left(\frac{a}{r}\right)^{n+1} P_n^m(\cos \theta) \quad (4)$$

where $a = 6371.2$ km is a reference radius, (r, θ, ϕ) are geographic coordinates, P_n^m are the associated Schmidt semi-normalized Legendre functions, $\{g_n^m, h_n^m\}$

are the Gauss coefficients describing internal sources, and N_{\min}, N_{\max} are the minimum, resp. maximum, degree and order of the spherical harmonic expansion.

For the core field models these are chosen to be $N_{\min} = 1, N_{\max} = 18$ and the time dependence of the Gauss coefficients $\{g_n^m(t), h_n^m(t)\}$ is parametrized using B-splines; however, the final product MCO.SHA.2_ contains a series of snapshot models (corresponding to order 6 splines and 6 months separation of the spline knots). Details of the data format, and how to transform back from the snapshot representation to the original spline representation, are given in the *Level-2 Product Definition Document* (Swarm Level 2 Processing System Consortium, 2013).

Core field model version MCO.SHA.2C is derived in the Comprehensive Inversion chain (see Sabaka *et al.* (2013)

for details), while model version MCO_SHA_2D is derived in the Dedicated Inversion chain (Rother *et al.*, 2013).

A proper determination of the **Euler angles** α , β , γ describing the rotation between the instrument frames of the vector magnetometer and star tracker (see Eq. (2)) is only possible in-orbit. A pre-flight determination made on ground is limited e.g. by atmospheric turbulence to an accuracy of, say, 20 arc-seconds since global data coverage is required in order to obtain Euler angles within a few arc-seconds. This is only possible in-orbit. A determination of the Euler angles by co-estimation with all major contributions to the near-Earth magnetic field is made in the Comprehensive Inversion chain (Sabaka *et al.*, 2013), and an independent determination is made in the Dedicated Core chain (Rother *et al.*, 2013). The resulting Euler angles are provided as Level-2 data product MSW_EUL_2_ (MSW_EUL_2C and MSW_EUL_2F) and will be used in the re-processing of Level-1b data by the PDGS.

Spherical Harmonic Models of the **lithospheric field** are provided in the Level-2 product MLT_SHA_2_ (where “LT” stands for **L**ithospheric field). Similar to the core field products, model version MLT_SHA_2C is derived in the CI chain, while model MLT_SHA_2D is determined using the Revised Spherical Harmonic Cap method, as described in Thébaud *et al.* (2013). The minimum, resp. maximum, spherical harmonic degree and order is $N_{\min} = 16$ and $N_{\max} = 150$.

A model of the non-polar **daily geomagnetic variation caused by ionospheric currents**, including their variability with season and solar flux, is given in the Level-2 product MIO_SHA_2_, where “IO” stands for **I**onospheric field. Details of the dedicated chain leading to product version MIO_SHA_2D are given in Chulliat *et al.* (2013). Product version MIO_SHA_2C is derived in the CI chain.

Finally, time-series of spherical harmonic expansion coefficients of the **large-scale magnetospheric field** and its Earth-induced counterpart are provided in the Level-2 product of generic name MMA_SHA_2_. As part of the CI chain time series of the magnetospheric and induced expansion coefficients are provided with a sampling rate of 90 minutes (corresponding approximately to the orbital period of the satellites) for degree $n = 1$ and order $m = 0$, and with a sampling rate of 6 hours for degrees up to $n = 3$ and order $m = 0, 1$ for the magnetospheric field and up to $n = m = 5$ for the induced field. The name of the resulting product is MMA_SHA_2C. The dedicated chain (Hamilton, 2013) for deriving a related product called MMA_SHA_2F contains time series of magnetospheric and induced fields for degree $n = 1$ and order $m = 0, 1$ with sampling rate of 90 minutes. (The last character “F” in the product name indicates that this is a fast-track product which is provided without an independent regular validation as is the case for most other Level-2 products).

Level-2 data product MMA_SHA_2C of the large-scale magnetospheric field and its Earth-induced counterpart is used to determine **models of electrical conductivity of the mantle**, regarding both its 1-D structure (which means that conductivity is assumed to only vary with depth, resulting in Level-2 product MIN_1DM_2_, see Püthe and Kuvshinov (2013a) for details) and lateral

variations of conductivity (3-D models, Level-2 product MIN_3DM_2_). The latter is derived using two independent chains, working in the frequency domain, leading to product version MIN_3DM_2a (Püthe and Kuvshinov, 2013b), or in the time domain, leading to product version MIN_3DM_2b (Velínský, 2013). Electromagnetic transfer functions (*C*-responses) are also provided (Level-2 products MCR_1DM_2_ and MCR_3DM_2_).

3.2 Level-2 products related to acceleration, orbit determination and thermospheric wind and density

Precise reduced-dynamic and kinematic orbit solutions for the three *Swarm* satellites are provided in the Level-2 products SP3xCOM_2_ and SP3xKIN_2_. As part of this POD processing chain also the accelerometer calibration parameters (product ACCxCAL_2_) as well as non-gravitational accelerations (ACCxPOD_2_) are determined. Time series of thermospheric winds and density at the location of each of the three *Swarm* satellites are provided in the Level-2 product DNSxWIND_2_. Details of the processing scheme are given in Visser *et al.* (2013). The data flow of the two chains that result in these Level-2 products is shown in Fig. 4.

3.3 Level-2 products related to the Earth environment and space weather (Cat-2 products)

Figure 5 shows the processing chains that result in the Cat-2 Level-2 products (listed in the bottom part of Table 3). All Cat-2 products are provided as daily CDF files (similar to most of the Level-1b products) since they all contain time-series of a certain geophysical quantity.

Time series of an **Ionospheric Bubble Index (IBI)**, derived using magnetic and plasma observations from each of the three satellites, are provided in IBIxTMS_2F. Details of the processing can be found in Park *et al.* (2013). Time series of the ionospheric and plasmaspheric **Total Electron Content (TEC)** as determined by each of the three satellites are provided in the product TECxTMS_2F. The implemented algorithm for TEC determination is identical to that described by Noja *et al.* (2013). The processing schemes resulting in time series of **Field-Aligned Currents (FAC)** as provided in FACxTMS_2F (single satellite solution), resp. FAC_TMS_2F (obtained by combining data from *Swarm* A and B) are described in Ritter *et al.* (2013).

Dayside Eastward **Equatorial Electric Field (EEF)** values are derived for each equatorial crossing of each satellite ($x = A, B, \text{ or } C$) and are provided in the product EEFxTMS_2F. More details on that chain are given in Alken *et al.* (2013).

4. Development and Test of the Swarm SCARF

The various Cat-1 chains of SCARF have been tested using synthetic Level-1b data from a full 4.5 year long simulation of the *Swarm* mission. Since it is very difficult, if not impossible, to verify product requirements in-orbit with real data (because the reference models, the “true world”, which are needed to compare the estimated models with, are not known) the performance of each chain has been investigated using synthetic data. The quality of the estimated magnetic Level-2 products is assessed against the performance requirements as listed in Table 4 using the same criteria as in the similar study of Olsen *et al.* (2006):

Fig. 4. Level-2 processing chains that result in precise orbits and thermospheric Level-2 products.

Fig. 5. Level-2 processing chains related to the Earth environment and space weather (Cat-2 products).

Fig. 6. Left: Local Time, Local Time difference between the upper satellite and the lower pair. Right: satellite altitude vs. time.

- **Difference in spectra, degree error, and accumulated error.** The Mauersberger-Lowes spectrum (degree variance)

$$R_n(r) = (n + 1) \left(\frac{a}{r}\right)^{2n+4} \sum_{m=0}^n [(\Delta g_n^m)^2 + (\Delta h_n^m)^2] \quad (5)$$

of the differences between the true (i.e. input) and the estimated model coefficients, Δg_n^m , Δh_n^m , in combination with the spectrum of the input model, has been used to evaluate an estimated model. Degree error is defined as $\sqrt{R_n}$, and accumulated error at degree N is defined as $\sqrt{\sum_{n=n_{\min}}^N R_n}$.

- **Degree correlation**

$$\rho_n = \frac{\sum_{m=0}^n [g_{n,e}^m g_{n,t}^m + h_{n,e}^m h_{n,t}^m]}{\sqrt{\sum_{m=0}^n [(g_{n,e}^m)^2 + (h_{n,e}^m)^2] \sum_{m=0}^n [(g_{n,t}^m)^2 + (h_{n,t}^m)^2]}} \quad (6)$$

(Langel and Hinze, 1998, eq. (4.23)), where $g_{n,e}^m$ and $h_{n,e}^m$ are from the estimated model and $g_{n,t}^m$ and $h_{n,t}^m$ are from the input model, has also been used to evaluate a spherical harmonic model. Models are considered compatible up to that degree n where ρ_n drops below 0.7.

- **Sensitivity matrix** is the relative error of each coefficient in a degree versus order matrix:

$$S(n, m) = \begin{cases} 100 \frac{h_{n,e}^m - h_{n,t}^m}{\sqrt{\frac{1}{2n+1} \sum_{m=0}^n [(g_{n,t}^m)^2 + (h_{n,t}^m)^2]}}, & \text{for } m < 0 \\ 100 \frac{g_{n,e}^m - g_{n,t}^m}{\sqrt{\frac{1}{2n+1} \sum_{m=0}^n [(g_{n,t}^m)^2 + (h_{n,t}^m)^2]}}, & \text{for } m \geq 0. \end{cases} \quad (7)$$

$S(n, m)$ represents the percentage degree-normalized error in a recovered coefficient of degree n and order m .

- **Global maps** of field differences (for instance of B_r) between the input and the estimated model are used to find geographically confined deficiencies in the estimated models, for instance in connection with the polar gaps.
- Finally, the quality of time series (like those of the magnetospheric and induced spherical harmonic expansion coefficient) is assessed for various target periods using **Squared Coherency** coh^2 : If $F(\omega)$ and $G(\omega)$ are the Fourier transform of the two time series $f(t)$ and $g(t)$ and $F(\omega)^*$ is the complex conjugate of $F(\omega)$ then squared coherency at frequency ω is defined as

$$\text{coh}^2 = \frac{\langle F(\omega)G(\omega)^* \rangle \langle G(\omega)F(\omega)^* \rangle}{\langle F(\omega)F(\omega)^* \rangle \langle G(\omega)G(\omega)^* \rangle} \quad (8)$$

with $\langle F(\omega)G(\omega)^* \rangle$ and $\langle G(\omega)F(\omega)^* \rangle$ as the cross-spectra and $\langle F(\omega)F(\omega)^* \rangle$ and $\langle G(\omega)G(\omega)^* \rangle$ as the auto-spectra of $f(t)$, $g(t)$ (e.g. eq. (20) of Olsen, 1998).

At the beginning of the SCARF activity the launch of the *Swarm* satellites was still scheduled for 2010. In order to have similar ambient conditions, but access to actual input values to parametrize e.g. atmospheric drag or Earth rotation variations, we simulated a launch on July 1, 1998, 00:00 UT, which is approximately one solar cycle (11 years) before the anticipated launch in 2010.

The performed simulation is described in more detail in Olsen *et al.* (2007), which is an extension of the work of Olsen *et al.* (2006). In a first step we calculated synthetic orbits. We assumed all three satellites to be in circular near-polar orbits with injection altitude of $h_0 = 450$ km altitude and orbital inclination $i = 87.4^\circ$ for the lower pair (*Swarm* satellites A and B) and of $h_0 = 530$ km altitude and orbital inclination $i = 88^\circ$ for the third satellite *Swarm* C. The two lower satellites were assumed separated in longitude by 1.4° . They are not exactly side-by-side (which would imply collision risk near the poles) but are shifted along-track by a time lag between 2 and 10 seconds. This simulates the requirement that “The maximum time difference between *Swarm* A and *Swarm* B when crossing the equator shall be 10 seconds”. The chosen orbital configuration is similar (though not identical) to the one that is presently foreseen for *Swarm* ($h_0 = 460$ km and $i = 87.35^\circ$ for *Swarm* A and B; $h_0 = 530$ km and $i = 87.95^\circ$ for *Swarm* C, and a Local Time of the Ascending Node of about 14:30).

In order to get a lifetime of 4.5 years duration for the lower pair we included four orbit manoeuvres—similar to the ones of the CHAMP satellite: we increased the altitude of *Swarm* A and B by 15 km on April 1, 2001 and September 1, 2001, respectively, and by 12 km on November 15, 2001 and April 1, 2002, respectively. The obtained Local Time, the Local Time difference between the upper satellite and the lower pair, and satellite altitude as a function of time are shown in Fig. 6.

Magnetic field data generation follows mainly the approach described in Olsen *et al.* (2006) with updates given in Olsen *et al.* (2007). The various input models have been designed in the following way: The core field is taken from the GRIMM model (Lesur *et al.*, 2010) for the years 2003 to 2008, but shifted by 5 years (i.e. to 1998.0 to 2003.0) in order to be compatible with the simulation period. The lithospheric input model contains spherical harmonic expansion coefficients up to degree and order 250. Degrees $n = 14$ and 15 are taken from model POMME-6.1, degrees $n = 16$ to 90 are taken from model MF7, and degrees 91 to 250 are taken from model NGDC-720 (version 3p1) scaled by factor 1.1. See <http://geomag.org/models/index.html> for more information on these models. The magnetospheric field contribution is simulated using an hour-by-hour spherical harmonic analysis of world-wide distributed observatory hourly mean values of the years 1997–2002 in dipole-latitude and magnetic local time. Expansion coefficients of degrees $n = 1, \dots, 3$ and order $m = 0, \dots, 1$ have been determined. Secondary, Earth-induced fields are determined (up to $n = 15$) from those primary coefficients using the 3D mantle conductivity model, including oceans, discussed in Kuvshinov *et al.* (2006). The input model describing the ionospheric primary field is taken from CM4

Table 4. Product requirements for magnetic Level-2 products.

Product	Target Requirement	Threshold Requirement
Core field (MCO), first time derivative (secular variation) at ground, $n = 2$ –16, averaged over time	1 nT/yr	3 nT/yr
Lithospheric field (MLI), accumulated error at ground, $n = 16$ –150	40 nT	120 nT
Ionospheric field (MIO), average relative error on ground	10% globally	10% at magnetic latitudes below $\pm 55^\circ$
Magnetospheric field (MMA)	Squared coherency $\text{coh}^2 > 0.8$, though > 0.95 for $n = 1$	Squared coherency $\text{coh}^2 > 0.8$, though > 0.75 for $n = 1$
Mantle conductivity (MIN)	1/2 order of magnitude error, though 1/4 order of magnitude at depths 400–1500 km	1 order of magnitude error, though 1/2 order of magnitude at depths 400–1500 km

(Sabaka *et al.*, 2004) while the secondary, induced, field is calculated from those primary coefficients using the same 3D mantle conductivity model as for the magnetospheric induced field. Finally, we added synthetic noise based on CHAMP experience. We assumed correlated random noise of standard deviation (0.1 0.07, 0.07) nT for (B_N , B_E , B_C), in agreement with the *Swarm* performance requirements.

The magnetic field vector in the Level-1b CDF files is given both in the NEC coordinate frame and in the VFM frame of the vector magnetometer. In order to transform the synthetic data to the VFM frame we have arbitrarily chosen the (input) Euler angles ($\alpha = -1724$, $\beta = 3488$, $\gamma = -6184$) arcsecs for *Swarm* A, ($\alpha = 808$, $\beta = -434$, $\gamma = -1234$) arcsecs for *Swarm* B and ($\alpha = 2222$, $\beta = 2991$, $\gamma = 3115$) arcsecs for *Swarm* C.

The various input (reference) models are available at <ftp.space.dtu.dk/data/magnetic-satellites/Swarm/SCARF/TDS-1/Reference/> while the synthetic 1 Hz Level-1b data product MAGx_LR files can be found at <ftp.space.dtu.dk/data/magnetic-satellites/Swarm/SCARF/TDS-1/Level1b/Mag/>. Further details of the results of the closed-loop modelling tests to check each chain meets the performance requirements can be found in the respective references and papers in this volume.

5. Swarm Processing Time-line and Data Availability

The processing of *Swarm* data into Level-1b and Level-2 products is generally performed as soon as the appropriate input data are available. As baseline, data from the *Swarm* satellites themselves are downlinked on a daily basis (a more frequent downlink, in particular for making *Swarm* data more suitable for space-weather applications, is under consideration), however, the various processing steps may require certain auxiliary data inputs and/or a significant time-span of *Swarm* input data in order to produce high quality output products. Consequently the *Swarm* data processing time-line is as follows:

- **Three days (72 hours) after downlink**
Swarm Level-1b data are processed
- **Next working day**
Swarm Level-2 Quick-Look (MAGx_QL_2_ and EFlx_QL_2_), Fast-Track Magnetospheric (MMA_SHA_2F) and all Cat-2 data products (which

require up to 2 hours of processing time) are processed

- **Up to three weeks later**

Swarm Level-2 Products regarding Precise Orbit Determination (SP3xCOM_2_), Accelerometer data (ACCxCAL_2_, ACCxPOD_2_, ACCxAE_2_), and Thermospheric (Neutral) Density and Winds (DNSxWND_2_), are processed

- **Every three months**

Swarm Level-2 Fast-Track core field and Euler angles products (MCO_SHA_2F and MSW_EUL_2F) are processed

- **Every year**

Every year—plus a few extra times in reduced form during the first year of the mission—the *Swarm* Level-2 magnetic models are estimated and evaluated. The estimations are performed in two parallel processing chains:

- The Comprehensive Inversion (MSW_EUL_2C, MCO_SHA_2C, MLI_SHA_2C, MMA_SHA_2C, MIO_SHA_2C) and Mantle Conductivity estimations (MIN_1DM, MIN_3DM, MCR_1DM, MCR_3DM) each with a processing time of one month
- The Dedicated Inversions consisting of (in sequence, each step with a processing time of one month)
 - * Core field inversion (MCO_SHA_2D)
 - * Lithospheric field inversion (MLI_SHA_2D)
 - * Ionospheric field inversion (MIO_SHA_2D).

All estimated models are subject to an evaluation and—when parallel models are available—cross-comparisons which will be documented in the *Swarm* Level-2 Validation Products (Myy_VAL_2_) with a processing time of up to one month.

Level-1b and Level-2 data are available at <http://earth.esa.int/swarm>.

6. Conclusions

The *Swarm* mission is devoted to provide the best ever absolute measurements of the geomagnetic field. Its various instruments have been selected in order to optimize the scientific interpretation of the measurements in terms of the various sources of the magnetic field. In recognition of the large effort needed to extract the various types

of scientific information from the complex set of observations a group of institutions and organisations have joined the *SMART* consortium (*Swarm Magnetic and Atmospheric Research Team*). The consortium has decided to contribute to the optimal science return from the mission by supporting the creation of a *Swarm SCARF (Satellite Constellation Application and Research Facility)*, with the purpose of deriving commonly used scientific models and parameters, the so-called Level-2 products and make them available to the scientific community at large.

During the 3-year long development phase of *SCARF* the various processing chains have been optimized and thoroughly tested, demonstrating that the facility is ready to enter the data exploitation phase and process real *Swarm* data. It is believed that some of the results of the *SCARF* exercise may also be of relevance for future Earth Science constellation missions that undoubtedly will be implemented.

Acknowledgments. The Development of *Swarm SCARF* has been funded by ESA through contract No. 4000102140/10/NL/JA.

List of Acronyms

ASM	Absolute Scalar Magnetometer (instrument)
CDF	Common Data Format (Goucher and Mathews, 1994)
CI	Comprehensive Inversion
CRF	Common Reference Frame (of Star Tracker)
DI	Dedicated Inversion
EFI	Electric Field Instrument (LP and TII)
FAC	Field-Aligned Currents
GPS	Global Position System (Receiver)
ITRF	International Terrestrial Reference Frame
LP	Langmuir Probe (instrument)
NEC	North, East, Center coordinate frame
MOD	Medium Precise Orbit Determination
POD	Precise Orbit Determination
PDGS	Payload Data Ground Segment
RINEX	Receiver Independent Exchange Format (Gurtner and Estery, 2007)
SP3	National Geodetic Survey Standard GPS Format (Hilla, 2007)
STR	Star Tracker (instrument)
TEC	Total Electron Content of ionosphere
TII	Thermal Ion Imager (instrument)
VFM	Vector Field Magnetometer (instrument)
