ABSTRACT

Actuators based on dielectric elastomers have promising applications in artificial muscles, space robotics, mechatronics, micro-air vehicles, pneumatic and electric automation technology, heating valves, loud speakers, tissue engineering, surgical tools, wind turbine flaps, toys, rotary motors, and grippers for material handling, etc. This paper focuses on the application of Dielectric Electro Active Polymer (DEAP) technology as an actuation mechanism for different applications. The DEAP material requires very high voltage (~2.5 kV DC) to fully utilize it as an actuator. In this paper the DEAP actuator is analyzed in detail and the actuator structures, for the wind turbine flap and the heating valve applications are shown. Different high voltage switch mode power supply topologies for driving the DEAP actuator are discussed. The simulation and experimental results are discussed.

1 INTRODUCTION

Smart materials which respond to external stimuli like light, temperature, pressure, pH, magnetic and electric fields by changing their shape or size have been a particular focus in the past decade [1]. The intelligent materials include, shape memory alloys, piezoelectric materials, etc. and deforming active polymers include hydro gels, dielectric elastomers, carbon-nano tubes and liquid crystalline elastomers. Electro Active Polymers (EAPs) that undergoes force and deformation when electrically stimulated were strongly focused in the last years.

An actuator is a mechanical device for moving or controlling a mechanism or a system. EAPs can be used as actuators in active structures, in particular when large deformations are required. Such EAP actuators convert electrical energy into mechanical energy and produce large strains. Several applications of dielectric elastomer actuators were discussed in [2]. From the electrical standpoint, DEAP actuators are capacitive loads. In [3] a low voltage driven DEAP actuator was developed using piezoelectric transformer. A novel activation strategy for dielectric elastomer actuators was proposed in [4]. Section 2 discusses the detailed analysis of the DEAP actuator and its electrical, mechanical, and

electromechanical modeling, and the actuator structures for the heating valves and wind turbine flaps applications. We discuss the high voltage DC-DC converter topologies in Section 3, followed by the conclusion in Section 4.

2 DIELECTRIC ELASTOMERS AS ACTUATORS

Electro Active Polymers (EAPs) are categorized into two major classes: ionic and electronic. An electric field or coulomb forces drive electronic EAPs, while the actuation mechanism for ionic EAPs is through the diffusion or mobility of ions. The electronic EAPs generally require high electric fields ($>100 \text{ V}/\mu\text{m}$) and the ionic EAPs requires low driving voltages, nearly equal to 1-5V. Typical driving voltages for dielectric elastomer actuators lie in the range between 2 kV and 4 kV, depending on the polymer breakdown field and thickness of the polymer film. The operating principle of a dielectric elastomer actuator is shown in Figure 1. The DEAP material is a very thin ($\sim 40 \mu\text{m}$) incompressible elastomer film with a compliant electrode layer on both sides [5]. A dielectric elastomer is basically a compliant capacitor. The electrodes are designed to be able to comply with the deformations of the elastomer. As for any capacitor, when an electric field is applied to the electrodes, positive charges appear on one electrode, and negative charges on the other. This gives rise to coulomb forces between opposite charges, generating a pressure, known as the Maxwell stress. The Maxwell stress forces the electrodes to move closer, thereby squeezing the polymer. As the polymer is thinned, it elongates in the directions perpendicular to the applied force [6]. The electro static pressure (or stress) σ generated by the actuator is

$$\sigma = \epsilon_o \epsilon_r \left(\frac{v_{DEAP}}{x} \right)^2 = \epsilon_o \epsilon_r E^2 \quad (1)$$

where E is the imposed electrical field, x is the final thickness, v_{DEAP} is the voltage across the DEAP material, and ϵ_o and ϵ_r are the permittivity of the free space ($8.85 \times 10^{-12} \text{ F/m}$) and the relative permittivity of the polymer, respectively. The mechanical strain S of the DE is given by

$$S = -\frac{\epsilon_o \epsilon_r}{Y} \left(\frac{v_{DEAP}}{x_o / (1+S)} \right)^2 = -\frac{\epsilon_o \epsilon_r}{Y} \left(\frac{v_{DEAP} (1+S)}{x_o} \right)^2 \quad (2)$$

where Y is the Young's modulus and d_o is the initial thickness of the material. Using the capacitive behavior of the polymer, DEAP can be used as an actuator, mechano-electrical sensor, as well as energy harvester to generate electricity. When operated as an actuator DEAP show unique properties, such as very low electrical power consumption, high specific elastic energy density, high speed of response, no noise, flexibility, high power density, large bandwidth, higher performance than competing technologies and light weight, hence it has the potential to be an effective replacement for conventional actuators.

Figure 2. PolyPower DE tubular actuator

PolyPower™ dielectric elastomer (DE) is a silicone DE manufactured by Danfoss PolyPower A/S, Denmark. PolyPower DEAP actuator (Figure 2) is produced in thin sheets of $40 \mu\text{m}$ thickness. Table 1 shows the properties of the Danfoss PolyPower DEAP material. A DE sheet can be modeled as a strain dependent variable plate capacitor (3). For the unidirectional actuation shown in Figure 3, the capacitance of the DEAP actuator as a function of strain S is

$$C = \epsilon_o \epsilon_r \frac{A}{x} = \epsilon_o \epsilon_r \frac{A_o (1+S)}{x_o / (1+S)} = \epsilon_o \epsilon_r \frac{A_o}{x_o} (1+S)^2 \quad (3)$$

1.2 DEAP ELECTRICAL MODELLING

Figure 4a. Electric-circuit model of DEAP actuator

Figure 4b. Electric-circuit model of DEAP actuator including the inductance of the high voltage cables and the compliant electrodes

Figures 4a and 4b show the circuit representation of the electrical model for the DE system employed in this paper. In the figures, R_S is the resistance of the electrodes and the wiring, R_L is the resistance of the DE material, C is the capacitance of the DE sheet, L_S is the equivalent inductance of the electrodes and the high voltage cables, v_s is the voltage of the power source, and v_{DEAP} is the voltage over the DE sheet.

For the circuit shown in Figure 4a, the quasi-electrostatic pressure (1) at the surface of the DE sheet is induced by v_{DEAP} , which is given by

$$\frac{dv_{DEAP}(t)}{dt} + \left(\frac{R_L + R_S}{R_L R_S C} \right) v_{DEAP}(t) = \left(\frac{1}{R_S C} \right) v_s(t) \quad (4)$$

Similarly for the circuit shown in Figure 4b, the differential equations are given as,

$$v_s(t) = R_S i + L_S \frac{di}{dt} + v_{DEAP}(t) \quad (5)$$

$$i = \frac{v_{DEAP}(t)}{R_L} + C \frac{dv_{DEAP}(t)}{dt} \quad (6)$$

Figures 5a and 5b are the block diagram representations for the electrical equivalents of the DEAP actuator.

1.3 DEAP MECHANICAL MODELLING

Figure 6. Voigt-Kelvin's viscoelastic model with inertial force.

Dielectric polymers exhibit both elastic solid and viscous fluid characteristics. The viscoelastic behavior of the polymers can be modeled as linear elastic spring (E_0 , E_1 and E_2) and dashpot networks (η_1 and η_2). The viscoelastic behavior of the DE actuators can be predicted by a Voigt-Kelvin five-parameter model (Figure 6) [7]. The strain response $S(t)$ to a step-stress input σ of the five-parameter Voigt-Kelvin model is

$$S(t) = \sigma \left(\frac{1}{E_0} + \sum_{n=1}^2 \frac{1}{E_n} \left(1 - \exp\left(-\frac{t}{\tau_n}\right) \right) \right) \quad (7)$$

where $\tau_n = \eta_n / E_n$ are the retardation time constants.

1.4 DEAP ELECTRO-MECHANICAL MODELLING

Figure 7. Electro-mechanical modeling of DEAP actuator

Figure 7 shows the electro-mechanical model of DEAP actuator. The input voltage v_s generate a voltage across the DEAP capacitor v_{DEAP} , which induces an electrostatic pressure σ . The mechanical part input viz., the electrostatic pressure σ is the input that results in a mechanical strain S . If the actuation strain S is large, it changes the capacitance C , thickness t , and the stiffness of the material

2.5 DIFFERENT STRUCTURES OF DEAP ACTUATORS

In this paper we focus on the application of DEAP actuator technology to two challenging applications, viz., heating valves and wind turbine flaps. The actuator structures for the two applications are discussed below.

2.5.1 WIND TURBINE FLAP APPLICATION

Figure 8. Left: Embedded DEAP actuator into the wing flap; Right: actuated flap structure with DEAP actuators.

Implementing DEAP actuator in the wind turbine flaps will result in improved blade efficiency, reduced loads and fatigues

on the blades and turbine. Figure 8 shows the typical structure of the wind turbine flap with embedded DEAP actuators.

2.5.2 HEATING VALVE APPLICATION

Figure 9. The heating valve containing the DEAP actuator

The current heating valve actuators in the market are thermal actuators, being noiseless but consuming significant power, and electrical gear motors which are relatively energy efficient, but inherently prone to noise issues. The compact in-line heating valves based on DEAP actuator will make better, cheaper and noiseless valves without mechanical parts.

3 HIGH VOLTAGE POWER CONVERTERS TO DRIVE THE DEAP ACTUATOR

To drive the DEAP actuator a high voltage in the range of kilovolts is required [3, 4]. For the systematic control of the DEAP actuators that are implemented in a specific application, special high voltage power electronic (HVPE) converters with advanced control techniques are required. Simulation and experimental results for a unidirectional flyback converter are shown.

3.1 DIFFERENT TOPOLOGIES

Flyback and full bridge converters shown in Figures 10a and 10b, are some of the suitable DC-DC converter topologies for high voltage applications. However, the choice of the converter topology depends on the specific requirements of the application, which are shown in Table 2.

Table 2. Specifications of the applications and choice of converter topology

Application	Input voltage	Charging Time of Actuator
Wind turbine flap	24 V (from battery)	50-100 ms
	400 V (from wind turbine)	
Heating valve	3 V (from battery)	5-10 min

Table 3. Parameters of the flyback converter used in the experiment

Parameters	Values
Rated input voltage	24 V
Rated output voltage	2.5 kV
Magnetizing inductance L_p	35 μ H
Flyback transformer core	EF20, N87
Primary turns/ Turns ratio	10/ 20
Leakage inductance L_{lk}	800 nH
Capacitance of DEAP actuator	145 nF
Primary peak current	5.3 A

Figure 10a. Schematic of bi-directional flyback converter

Figure 10b. Schematic of isolated bi-directional full bridge converter.

In this paper we focus only on the flyback topology, for both applications. We used LT3751 capacitor charger controller to generate high voltage. However, for wind turbine flap application, if the output power requirement is too high, isolated full bridge converter is the good choice.

3.2 SIMULATION AND EXPERIMENTAL RESULTS

The simulation has been done using LTSpice software. The simulation results for a uni-directional flyback are shown below for different input voltages ($V_{in} = 3V, 24V$ and $400V$).

4 CONCLUSION

The DEAP actuator is analyzed in detail. And the modeling of the DEAP actuator is presented. Different structures of the DEAP actuators that can be implemented in two different applications are shown. Some high voltage converter topologies for driving the capacitive loads are presented. Finally, simulation and experimental results are shown for a uni-directional flyback converter.
